our framework in the context of online contention resolution schemes for matching with random-order vertex arrivals. For bipartite graphs with two-sided arrivals, we design a $(1+\sfe^{-2})/2 \approx 0.567$-selectable RCRS, which we also show to be \textit{tight}.
Next, we show that the presence of short odd-length cycles is the only barrier to attaining a (tight) $(1+\sfe^{-2})/2$-selectable RCRS on general graphs. By generalizing our bipartite RCRS, we design an RCRS for graphs with odd-length girth g which is $(1+\sfe^{-2})/2$-selectable as $g \rightarrow \infty$. This convergence happens very rapidly: for triangle-free
graphs (i.e., $g \ge 5$), we attain a $121/240 + 7/16 \sfe^2 \approx 0.563$-selectable RCRS.
Finally, for general graphs we improve on the $8/15 \approx 0.533$-selectable RCRS of (Fu et al., 2021) and design an RCRS which is at least 0.535-selectable.
Due to the reduction of (Ezra et al., 2020), our bounds yield a 0.535-competitive (respectively, $(1+\sfe^{-2})/2$-competitive) algorithm for prophet secretary matching
on general (respectively, bipartite) graphs under vertex arrivals.

2 - The Online Submodular Assignment Problem

Daniel Hathcock, Carnegie Mellon University, Pittsburgh, PA, United States, Billy Jin, Kalen Patton, Sherry Sarkar, Michael Zlatin

Online resource allocation is a rich and varied field. One of the most well-known problems in this area is online bipartite matching, introduced in 1990 by Karp, Vazirani, and Vazirani. Since then, many variants have been studied, including AdWords, the generalized assignment problem (GAP), and online submodular welfare maximization.

In this work, we introduce a generalization of GAP which we call the submodular assignment problem (SAP). This generalization captures many online assignment problems, including all classical online bipartite matching problems as well as broader online combinatorial optimization problems such as online arboricity, flow scheduling, and laminar restricted allocations. We present a fractional algorithm for online SAP that is (1 - 1/e)-competitive.

Additionally, we study several integral special cases of the problem. In particular, we provide a (1 - 1/e - \epsilon)-competitive integral algorithm under a small-bids assumption, and a (1 - 1/e)-competitive integral algorithm for online submodular welfare maximization where the utility functions are given by rank functions of matroids.

The key new ingredient for our results is the construction and structural analysis of a “water level” vector for polymatroids. This construction reveals connections to submodular utility allocation markets and principal partition sequences of matroids.

3 - Adaptive Policies and Approximation Schemes for Dynamic Matching

Ali Aouad, London Business School, London, United Kingdom, Alireza Amanihamedani, Amin Saberi

Motivated by applications to ride-hailing platforms and organ donation schemes, we study a dynamic matching problem, where customers and servers arrive according to Poisson point processes. Customers must be immediately matched to an available server within the network of queues, and servers renege after a random duration. The goal is to optimize the long-term average throughput and cost of the matches.

Previous literature on dynamic matching often focuses on static policies—where matching decisions are not adapted to dynamic information on the servers’ queue lengths. In this work, we formulate tighter linear programming (LP) approximations that represent an adaptive matching process, where the queue lengths inform the matching decisions in real time. This new LP allows us to develop a bi-criteria fully polynomial-time approximation scheme for single-queue instances. Using a lifted polyhedral relaxation, we devise a polynomial-time approximation schemes (PTAS) for instances with a constant number of server types. By combining this approach with careful instance decompositions, we devise the first PTAS for dynamic matching on fixed-dimensional Euclidean graphs.

4 - Online Submodular Welfare Maximization Meets Post-Allocation Stochasticity and Reusability

Rajan Udwani, UC Berkeley, Berkeley, CA, United States

We generalize the problem of online submodular welfare maximization to incorporate a variety of new elements arising from reusability, stochastic rewards, combinatorial actions and similar features that have received significant attention in recent years. For our general formulation, we show that a non-adaptive Greedy algorithm achieves the highest possible competitive ratio against an adaptive offline benchmark in the adversarial arrival model and also under some assumptions in the unknown IID stochastic arrival model. This generalizes several previous results and shows that, in general, adaptivity to stochastic rewards (and similar features) offers no theoretical (worst-case) benefits.

Pricing Aspects of Platform Design

Invited Session

Revenue Management and Pricing

Chair: Michael Hamilton, University of Pittsburgh, Pittsburgh, PA, United States

Co-Chair: Titing Cui, University of Pittsburgh, Pittsburgh, PA, United States

1 - Distance-Based Fee Design of Rapid Delivery

Manlu Chen, Renmin University of China, Beijing, China, People's Republic of, Mingliu Chen, Ming Hu, Jianfu Wang

This paper examines the evolving landscape of the rapid delivery service industry, focusing on the strategic variations in pricing structures and service offerings as firms expand their operations from urban to suburban areas. Utilizing a stylized queueing model, we analyze the effects of a two-part delivery price—which includes a base fee and a distance-dependent fee—alongside the availability of a self-pickup option. The study evaluates the implications of these strategies for various stakeholders across various customer density environments. In urban centers, our findings indicate that vendors target nearby customers, instituting a positive per unit distance fee to deter distant orders. This approach optimizes courier capacity for servicing nearby customers. In contrast, vendors operating in suburban settings aim to attract remote, high-valuation customers by introducing a negative per unit distance fee, effectively subsidizing delivery costs—a practice less favorable to customer welfare and social welfare. We further investigate the potential profitability of self-pickup as an alternative to delivery services. In densely populated urban areas, self-pickup proves more lucrative, leading vendors to incentivize this option through discounts. Conversely, in suburban regions with lower population densities, vendors may impose additional fees on self-pickup to favor delivery services. Our analysis concludes that, despite the varying profitability across demographic regions, the provision of a self-pickup option consistently benefits vendor profits and customer welfare. This research underscores the critical role demographic characteristics play in the strategic deployment of rapid delivery and self-pickup services, with significant implications for the operational and pricing strategies of firms within the industry.

2 - Fresh Rating Systems: Structure, Incentives, and Fees

Titing Cui, University of Pittsburgh, Pittsburgh, PA, United States, Michael Hamilton

Rating systems aggregate customer reviews into a numeric measure of service quality. However, not all reviews — and consequently, not all ratings — are equally informative. The relevance of a review diminishes as it ages, making older reviews less indicative of a service provider's current quality. Older, outdated reviews are often termed \textit{stale} and pose a number of challenges for traditional rating systems. Rating systems that do not consider the age of reviews may not accurately represent the current service quality, they are also more susceptible to manipulation, and can lead to perverse incentives for service providers.

In this paper, we explore how to modify rating systems to address the issue of stale reviews. We consider two types of staling, sequential staling and temporal staling. To mitigate issues due to sequential staling, we introduce a new class of $\al$-moving average rating systems which systematically down-weight older reviews. We show that the moving average approach generates ratings in a way which optimally protects customers from changes in the underlying quality of service that may otherwise go undetected due to staling. To address issues due to temporal staling, we extend our rating system to include penalty ratings that are incurred by long periods of inactivity. In a model of online platforms that facilitate interactions between service providers and customers, we give a prior-free way of choosing the penalty term and associated parameters which approximately maximizes revenue and also discourages users and providers from disintermediating on the platform.

3 - The Power of Two in Token Systems

Süleyman Kerimov, Rice University, Houston, TX, United States, Itai Ashlagi, Omer Tamuz

In economies without monetary transfers, token systems serve as an alternative to sustain cooperation, alleviate free riding, and increase efficiency. This paper studies whether a token-based economy can be effective in marketplaces with thin exogenous supply. We consider a marketplace in which at each time period one agent requests a service, one agent provides the service, and one token (artificial currency) is used to pay for service provision. The number of tokens each agent has represents the difference between the amount of service provisions and service requests by the agent. We are interested in the behavior of this economy when very few agents are available to provide the requested service. Since balancing the number of tokens across agents is key to sustain cooperation, the agent with the minimum amount of tokens is selected to provide service among the available agents. When exactly one random agent is available to provide service, we show that the token distribution is unstable. However, already when just two random agents are available to provide service, the token distribution is stable, in the sense that agents' token balance is unlikely to deviate much from their initial endowment, and agents return to their initial endowment in finite expected time. Our results mirror the power of two choices paradigm in load balancing problems. Supported by numerical simulations using kidney exchange data, our findings suggest that token systems may generate efficient outcomes in kidney exchange marketplaces by sustaining cooperation between hospitals.

4 - Price Parity and Competition on E-Commerce Platforms

Yi Tong, University of Florida, Gainesville, FL, United States, Jingchuan Pu, Quan Zheng

To prevent marketplace leakage, e-commerce platforms usually enforce a price parity clause on third-party sellers, forbidding them from offering lower prices elsewhere online, including their own websites. Regulators have criticized this requirement as an anti-competitive practice detrimental to sellers and consumers. In this study, we examine the marketplace's incentives for implementing price parity and investigate its impacts on sellers and consumer welfare under different market conditions, providing timely insights for policymakers. Along with the price parity, the marketplace's introduction of its own brands is also widely criticized due to the intensified competition faced by third-party sellers. Against this backdrop, we first examine the impact of the marketplace's own brand and price parity on sellers and consumers. We further analyze whether and how these two retail arms interplay.

Advancements in Network Management and Analysis

Contributed Session

Chair: Feiran Xu, University of Iowa, Iowa City, IA, 52242, United States

1 - Approximation Algorithms for Directed Weighted Spanners and Buy-at-bulk Network Design

Young-San Lin, Melbourne Business School, Carlton, Australia, Elena Grigorescu, Nithish Kumar

We present efficient sublinear-factor approximation (online) algorithms for directed pairwise weighted spanners and buy-at-bulk network design, where each edge is associated with a cost and a length. The goal is to find a minimum-cost subgraph that satisfies terminal distance constraints.

2 - Convolutional Similarity Network Fusion on Multiplex Graphs

Sangheum Cho, Ajou University, Suwon, Korea, Republic of, Taehwan Yun, Hyunjung Shin

Multiplex graphs denote a collection of graphs that share the same set of nodes but possess different sets of edges, depending on the data source. As data availability grows, utilizing data with diverse source information, such as multiplex graphs, becomes increasingly important. In particular, if each graph that makes up multiplex graphs has complementary information, it can contribute to better performance of machine learning models. Despite this advantage of complementary information, recent research on graph-based deep learning models has mainly focused on dealing with single graph rather than multiplex graphs. Therefore, we propose deep learning framework specialized for multiplex graphs using the Similarity Network Fusion (SNF) algorithm, which is one of the integration methods for structured data. In our proposed method, SNF is extended to the problem of multiplex graphs by exploiting the embedding process with graph convolution. As a results of experiments on toy and real-world datasets, the proposed method showed significantly better performance than comparison methods, and especially maintained high performance even in situations where there is little labeled data.

3 - Sensor Placement Strategy Under Limited Budget for Anomaly Detection in Large Scale Networks

Feiran Xu, University of Iowa, Iowa City, IA, United States, Ramin Moghaddass

Large-scale graph-structured systems are becoming increasingly prevalent, and it is typically essential important to maintain their stability and reliability. One key challenge in ensuring this reliability is the timely detection of anomalous nodes and the identification of the original sources of disturbances. Reading and analyzing the real-time sensor data from within the network can facilitate this task. However, the limited availability of sensors poses a significant constraint, as it is impractical to deploy sensors at every node. Therefore, determining the optimal placement of a limited number of sensors to maximize system observability is a fundamental yet challenging problem. This work introduces an innovative cluster-based framework designed to identify an optimal set of nodes for sensor placements for anomaly detection within a large-scale network. The proposed method is evaluated through a series of data experiments, demonstrating its effectiveness in enhancing network observability under budget constraints.

4 - Strategic Risk and Cost Reduction in Transportation Networks: a Data-Driven Optimization Approach

Zeinab Vosooghi, McMaster University, Hamilton, ON, Canada, Manish Verma

This study presents an innovative methodology for identifying critical zones within a transportation network, with a specific focus on hazardous material (hazmat) transportation. By employing a data-driven optimization-analytics approach, the aim is to minimize both the cost and risk associated with hazmat railroad transportation problems. Initially, a comprehensive nationwide risk assessment is conducted for Class 1 railroads across the United States, utilizing data mining techniques applied to the Federal Railroad Administration (FRA) dataset on hazardous material-related accidents. This analysis facilitates the development of a robust predictive model for estimating the likelihood and damages of future accidents. Subsequently, strategic areas within the network are identified by solving a bi-objective model that seeks to minimize both network cost and risk. The integration of well-established methodologies such as weighted sum and epsilon constraint enhances the reliability of the results, which are subsequently validated.

Practical Applications of Decision Analysis

Invited Session

Decision Analysis Society

Chair: luis lillo, Pontificia universidad Catolica de Valparaiso, santiago, Chile

1 - Dynamic analysis for predicting the hydraulic performance of the wine bottling system based on operational and comprehensive indicators.

Luis Lillo, Pontificia universidad Catolica de Valparaiso, Valparaiso, Chile, Hanns De la Fuente, Jose Ceroni

The wine industry in Chile has significant socio-cultural and economic importance. However, it faces challenges such as climate change, declining consumer preferences compared to other products, and a constant increase in costs, especially in energy and labor. In this context, the final filtration stage before bottling is crucial due to its high cost and variability, as well as its role in ensuring microbiological stability and organoleptic attributes through particle retention that can alter the wine's properties. Particle retention reduces the available filtering area, increases the pressure differential, and gradually decreases the flow, affecting the bottling speed to levels that may render the process unfeasible. Traditionally, the tools and strategies of the industry do not allow for timely forecasting of these situations, impacting the production plan and costs.

In response to these challenges, a machine learning model has been developed and evaluated for dynamic analysis and prediction of the hydraulic performance of the filtration and bottling system, taking into account the physicochemical properties of the wine, comprehensive indicators, and the measurement of operational parameters. This model is designed to estimate the efficiency of the filter media and the flow evolution during the bottling process, enabling the estimation of bottling time and planning of cleaning processes or line stoppages due to filter media fouling. With this, the aim is to improve operational decision-making during bottling, allowing for more effective control of costs and their variability through the use of adaptable and reliable tools with potential for industry-wide application.

.

2 - Investment challenges under renewable variability and water scarcity for the operation of microgrids.

Yolanda Matamala, Universidad Católica de la Santísima Concepción, Concepción, Chile, Kevin Melendez

Investing in Power-To-X technologies could prove infeasible considering challenges such as, 1) The future of energy development could soon be limited by water scarcity. 2) The variability of renewable sources poses challenges to the electrical grid in a scenario of growing demand and climate change events. 3) Economic viability associated with the high investment costs in flexible technologies or infrastructure. This study propose a strategic plan for the feasibility of investment in Power-To-X technologies under water scarcity scenarios for microgrid communities in connected mode. The interaction of microgrids is modeled through a stochastic bi-level model that considers water availability constraints. The results show that stochastic planning allows for more fluid electricity and hydrogen production and storage strategies, ensuring consistent operations with a narrower production range. The information obtained could be used to contribute to public policies that consider financing sustainable development for microgrid communities.

3 - A MIP Formulation for the Bottling Scheduling Problem in the Wine Industry with Sequence-Dependent Setup Times

Alonso Peña Domarchi, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile, Luis Lillo, Hanns de la Fuente, Abhishake Kundu

A systematic review has revealed a gap in the wine industry: the planning of the bottling process and the complexities of the filtering stage have not been addressed simultaneously. In response to this, a novel optimization model will be formulated using Mixed Integer Programming (MIP) for the last stage of the production process. The objective is to minimize production times, considering the interdependencies of operational decisions and the specific conditions of the bottling and filtering processes in the wine industry. The model can be considered a scheduling of jobs to production lines with sequence-dependent setup times. To test the applicability of the model, data from one of the largest wineries in the Chilean wine industry will be used. Computational experiments will be developed to create an algorithm that solves the additional complexity of larger instances.

4 - A Two-Stage Stochastic Optimization Framework for Efficient Food Management in Hospitals

Mariana Arriz Jorquiera, University of South Florida, Tampa, FL, United States, Jorge Acuna, Jose Zayas-Castro

Food waste in healthcare systems presents a significant environmental and nutritional challenge, contributing up to 5% of global environmental damage and impacting patient nutrition. This study introduces a two-stage stochastic optimization framework that minimizes food cost and waste in hospital settings. In the initial stage, the model estimates food requirements for the upcoming week. Subsequently, the model builds the meals for the patients considering diverse dietary needs, demographics, and three possible demand scenarios. Our approach integrates flexibility by accounting for last-minute purchases to address shortages and managing inventory surplus efficiently. The stochastic nature of the model is driven by the probabilities associated with each scenario, determined by the distribution of the patient's length of stay. This integration of stochasticity enhances the model's resilience against unforeseen fluctuations in demand, improving the efficiency and effectiveness of food procurement and distribution in hospital settings. Overall, this framework offers economic benefits for the hospital and contributes to environmental sustainability and patient well-being.

5 - Optimizing Kidney Transplant Allocation in the US: A Two-Stage Stochastic Approach

Daniela Cantarino, University of South Florida, Tampa, FL, United States, Jorge A. Acuna, Jose Zayas-Castro

Chronic kidney disease (CKD) presents a significant challenge to the United States' population, impacting longevity and quality of life. Renal transplants offer a pivotal intervention, extending life expectancy by an average of 10 years compared to dialysis. However, the persistent shortage of viable kidneys highlights the urgent need for more efficient allocation strategies. To address this, we propose a novel multi-period two-stage stochastic model aimed at improving the quantity and quality of matches by focusing on pre- and post-transplant processes. The model accounts for uncertain parameters and evaluates key considerations such as waitlist mortality, expected survival rates, travel distances, organ degradation, and biological compatibilities. By running simulations, we calculate Quality-Adjusted Life Years (QALYs) to assess the effectiveness of different allocation strategies, providing valuable insights for enhancing the efficiency and equity of the kidney transplant system.

6 - Bilevel programming methods for hyperparameter optimization in support vector machines: A classification and regression approach

Gonzalo Ríos, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile, Hanns de la Fuente-Mella, Felipe Feijoo

Support vector machine (SVM) is a classical model well known for its performance as a learning method for regression and classification tasks in a wide range of problems that require machine learning tools. In this study we introduce a novel framework with a reformulation for hyperparameter selection in SVM for support vector regressor (SVR) and support vector classifier (SVC) with bi-level programming models, both in SVR and SVC the upper-level problem minimizes the error for predicted values, considering misclassification metrics for SVC and mean absolute error for SVR, while the lower-level problems set the values for parameters and hyperparameters on the entire model. The bi-level problem is converted to a mathematical program with equilibrium constraints (MPEC) model. The MPEC is solved by applying Karush-Kuhn-Tucker (KKT) conditions over the lower–level problems and the nonlinear constraints derived from complementary conditions on KKT / MPEC are linearized by using the Big-M method and special ordered set type 1 (SOS1) variables. In experiments the models and reformulations are tested against public and simulated datasets with different shapes, showing the model reformulated and linearized through SOS1 variables is faster than the one linearized with the Big-M method. Results provide evidence, not only of the efficiency shown by the model reformulated with SOS1 variables against the Big-M method but also of the differences of a bi-level approach against classical machine learning model approaches commonly used in the professional and scientific community.

1 - Multistorage - Power vs. Energy - When To Transition Between Storage Technologies

Christian Kaps, Harvard Business School, Cambridge, MA, United States, Simone Marinesi

As the world transitions towards a decarbonized energy future, the choice of energy storage technologies plays a pivotal role in matching the variable supply of renewable generation with demand. In this paper, we model the trade-off between different storage technologies, focusing on the difference between how much energy a technology can store and how much power it can provide at any given time. This distinction is crucial as the use cases for and cost of large-scale energy storage technologies differ.
along these dimensions in drastic ways, impacting under which circumstances they can be operated profitably.

With this paper, we aim to answer three research questions: i) What factors determine the utilization of a given storage technology; b) how does the duration for which energy needs to be stored (hours, days, weeks, seasons) impact which storage technology is most useful; c) how does the existence of multiple storage technologies impact the value or utilization compared to each technology in isolation?

2 - Renewable, Flexible, and Storage Capacities: Friends or Foes?

Owen Wu, Indiana University, Bloomington, IN, United States, Xiaoshan Peng, Gil Souza

Over 99% of the new power generation capacity to be installed in the U.S. from 2023 to 2050 will be powered by wind, solar, and natural gas. Additionally, large-scale battery systems are planned to support power systems. It is paramount for policymakers and electric utilities to deepen the understanding of the operational and investment relations among renewable, flexible (natural gas-powered), and storage capacities. In this paper, we optimize both the joint operations and investment mix of these three types of resources, examining whether they act as investment substitutes or complements. Using stochastic control theory, we identify and prove the structure of the optimal storage control policy, from which we determine various pairs of charging and discharging operations. We find that whether storage complements or substitutes other resources hinges on the operational pairs involved and whether executing these pairs is constrained by charging or discharging. Through extensive numerical analysis using data from a Florida utility, government agencies, and industry reports, we demonstrate how storage operations drive the investment relations among renewable, flexible, and storage capacities. Storage and renewables substitute each other in meeting peak demand; storage complements renewables by storing surplus renewable output; renewables complement storage by compressing peak periods, facilitating peak shaving and displacement of flexible capacity. These substitution and complementary effects often coexist and the dominant effect can alternate as costs change. A thorough understanding of these relations at both operational and investment levels empowers decision-makers to optimize energy infrastructure investments and operations, thereby unlocking their full potential.

3 - Breaking the utility death spiral: A regime-switching fee-based model for utilities firms serving customers with renewable energy generation

Alexandar Angelus, Texas A&M University, College Station, TX, United States

It is well established that utilities serving customers with distributed solar power generation face deteriorating profits due to the resulting demand reduction and frequently mandated net metering compensation for those customers' excess generated power. In this research, we propose a regime-switching fee-based mechanism that protects an electric utility from the impact of distributed renewable generation in the presence of net metering while still incentivizing customers' renewable energy investments. In the context of the infinite-horizon, sequential game played between a utility and its customer, we establish that this pricing mechanism can achieve perfect coordination of the supply chain consisting of a customer and his utility, and attain Pareto improvements in value function for both parties.

4 - Energy consumption of limited response to weather

Fariba Farajbakhsh Mamaghani, Tulane University, River Ridge, LA, United States, Saed Alizamir, Shouqiang Wang

The integration of smart technologies and automation into the power grid has empowered utility firms to monitor real-time consumption and experiment with price-based incentive mechanisms to mitigate demand-supply imbalances. However, recent implementations of Demand Response (DR) programs in residential sectors have yielded mixed results, challenging assumptions about consumer responsiveness to price signals. One major obstacle is the inability of fixed prices to account for exogenous factors like outdoor temperature fluctuations. This limitation leads to erratic energy demand patterns as households struggle to adjust consumption rationally. Addressing this, we propose a novel framework rooted in the concept of "rational inattention" to analyze households' decision-making processes. By considering cognitive limitations and information processing costs, we identify regions where households are responsive or non-responsive to demand shocks, driven by comfort or cost-saving motives. Our analysis reveals nuanced relationships between price, consumption variability, and overall market reliability. Using real data from New York City apartments, we calibrate our model to offer insights into empirical demand patterns. Our findings complement existing DR program analyses, providing utility firms and policymakers with normative recommendations for designing effective pricing mechanisms and anticipating market responses.

1 - Minimax-Regret Sample Selection in Randomized Experiments

Yuchen Hu, Management Science and Engineering, Stanford University, Stanford, CA, United States, Henry Zhu, Emma Brunskill, Stefan Wager

Randomized controlled trials are often run in settings with many subpopulations that may have differential benefits from the treatment being evaluated. We consider the problem of sample selection, i.e., whom to enroll in a randomized trial, such as to optimize welfare in a heterogeneous population. We formalize this problem within the minimax-regret framework, and derive optimal sample-selection schemes under a variety of conditions. Using data from a COVID-19 vaccine trial, we also highlight how different objectives and decision rules can lead to meaningfully different guidance regarding optimal sample allocation.

2 - Axiomatizing the Bayesian Paradigm in Parallel Small Worlds

Simon French, Alliance Manchester Business School, Manchester, United Kingdom

There is currently much interest in scenario-focused decision analysis (SFDA), a methodology that provides, among other things, supporting analyses in circumstances in which there are deep uncertainties about the future (that is, when experts and decision makers (DMs) cannot come to any agreement on some of the probabilities to use in a Bayesian model). This lack of agreement can mean that sensitivity and robustness analyses show that virtually any strategy may be optimal under the beliefs of one or more participants. Scenario-focused analyses fix the deep uncertainties at interesting values in different scenarios and conduct a (Bayesian) decision analysis within each. The results can be informative to the DMs, helping them understand different possible futures and their reactions to them. However, theoretical axiomatizations of subjective expected utility (SEU), the core of decision analysis, do not immediately extend to the context of SFDA. The purpose of this paper is to provide an axiomatization of SEU that supports SFDA. Scenarios have much in common with Savage’s concept of small worlds. We discuss the parallels and then explore two difficulties in extending his and other writers’ axiomatizations. The development of SEU offered here overcomes these difficulties. Throughout, attention is given to the implications of the theoretical development for the practice of decision analysis.

3 - Reflections on a Decision Analysis Career by 2024 Frank P. Ramsey Medal Winner

Samuel Bodily, University of Virginia, Charlottesville, VA, United States

The Medal honors Ramsey, who introduced decision theory, where probability, or degree of belief was made operationally meaningful as willingness to act. This year’s awardee found this broadly applicable. He will talk about his career research, manifested in scholarly articles; his work in practice, exemplified by consulting and applied articles for business and government audiences; and his teaching, exemplified by cases and technical notes for students, articles on teaching effectiveness, and building a teaching team.

Pricing and Revenue Management Problems in Supply Chain Networks

Invited Session

Revenue Management and Pricing

Chair: Chun Ye, Amazon.com, Seattle, WA, United States

Co-Chair: Goutam Kumar, Amazon, Seattle, WA, United States

1 - Bandit-based assortment strategies with application to ultra-fast delivery

Siyeon Kim, Amazon, Raleigh, NC, United States, Hunyong Cho, Jonathan Jonker, Lina Al-Kanj, Boran Hu, Greg Herman, Josiah Davis, Zachary Hervieux-Moore, Eric Laber

Ultra-fast delivery is becoming an increasing important component of e-commerce. However, an effective ultra-fast delivery offering requires a finely tuned distribution system. At the heart of this system is an assortment that is as lean as possible while meeting customer purchase intent. To ensure an assortment that adapts to evolving customer preferences and that accommodates an ever-changing catalog of possible items, the assortment must be continuously refined through judicious experimentation. We propose a bandit-based exploration strategy based on customer segmentation that ensures assortments are fresh, regional, and responsive to changing demand. We illustrate the proposed methodology through experiments with Amazon's Sub-Same Day delivery service.

2 - Dynamic Pricing via Reinforcement Learning in a Spot Marketplace.

Jacob Tutmaher, Amazon, Denver, CO, United States, Huiwen Jia, Priyanka Shende, Mohsen Moarefdoost, Philip Kaminsky

We develop reinforcement-learning-based pricing algorithms for a transportation load board. The algorithm modifies the prices of available loads dynamically to achieve a set of performance goals, such as minimizing the operation costs, encouraging the use of clean energy equipment, and attracting enough carriers to secure the transportation needs. The optimal pricing policy is closely related to carriers’ willingness to pay and thus can be affected by several elements, such as the overall status of freight industry and the existence of substitutable loads or competing carriers interested in the same load. We formulate this dynamic pricing problem as a Markov Decision Process (MDP) and solve for a dynamic pricing policy via offline reinforcement learning.

3 - Offer Selections Optimizer in Transportation Capacity Sourcing

Yaser Ghaedsharaf, Amazon, Bellevue, WA, United States, Mohsen Moarefdoost, Huiwen Jia, Philip Kaminsky

A marketplace platform is used to source last-minute transportation loads. If a load is not covered on the platform, it goes to a manual sourcing channel where an agent engages in negotiations with carriers. The current negotiation process is manual and lacks scientific guidance, leading to higher costs. This paper formulates the problem as a Markov Decision Process and develops a machine learning-based model to optimize the negotiation process, resulting in significant cost savings.

4 - Spot Market Pricing on Amazon Freight

Goutam Kumar, Amazon, Seattle, WA, United States, Adam Elmachtoub, Roger Lederman

Amazon Freight is a business unit at Amazon that moves freight for other shippers using Amazon's internal middle mile network. In this talk, we describe the machine learning and price optimization algorithms used to manage Amazon Freight spot market.

For this business, external shippers use a website to request a price quote for a specific origin-destination pair, get prices instantly, and then decide which option to book. Amazon Freight provides prices that varies across options. The execution costs and demand can vary widely across different quotes due to internal cost structure and overall freight market. The goal for Amazon Freight is to set prices for each quote in order to maximize a business objective.

In order to capture the customer's choice of different options with different prices, we employ Multinomial (MNL) choice model which has quote and price dependent features. We use quote features to segment the market into disjoint groups. We employ the Market Segmentation Tree (MST) algorithm, which creates a binary tree based on differences in choice behavior. To optimize prices, we leverage the structure of reference-price-effects MNL choice model to develop a fast two parameter heuristic.

From live A/B experiments, this new framework significantly outperformed the previous system which relied on a mix of machine learning and multi-armed-bandit techniques. The new system increases both profit and revenue and improves prediction accuracy. Moreover, this streamlined approach provides a robust platform to support future services of Amazon Freight.

1 - Optimal Scheduling Problems with Conflict Constraints: The Wine Fermentation Tanks Case

Alejandro Mac Cawley, Pontificia Universidad Católica de Chile, Santiago, Chile, Susan Cholette, Carlos Monardes, Sergio Maturana, Jorge Vera, Arturo Wenzel

Scheduling and production planning problems are significant for operations across different industries. These problems are challenging, but integer programming (IP) models can solve them. These models support the planner's decision-making to collect and combine the raw material and assign it to some processor during a planning horizon. The time representation into those models can complicate their resolution, especially when the models are time-indexed. This difficulty opens new opportunities to represent the time in the IP models. In this article, we proposed a non-time indexed formulation for a specific type of scheduling problem with the goal of improve the resolution time and handle bigger instances. Our case study is focused on the wine industry. The choices are based on the lot's size, the processors' capacities, the time windows to collect and combine lots, and processing times. We created different instances for this problem to compare the non-time-indexed formulation with another one, which is, in fact, a time-indexed one. We concluded that scheduling problems could be modeled with formulations different from the time-indexed one, which can be more efficient and solve larger scale problems.

2 - Title: Process control optimization with time-series foundation models: advantages, challenges and applications

Markus Ettl, IBM Research, Yorktown Heights, NY, United States, Chandra Reddy, Kanthi Sarpatwar, Wesley Gifford, Vinicius Lima, Dzung Phan, Stuart Siegel, Shivaram Subramanian, Pankaj Dayama, Vijay Ekambaram, Arindam Jati, Binny Samuel, Carlos Hoyos, Gururaj Sagarad, Jayant Kalagnanam

Process-control problems arising in industrial applications have long employed Model Predictive Control (MPC) methods to improve production processes. The estimation methods, for modeling the processes, range from purely physics-based first-principles models to purely data-driven models. With the advances in machine-learning methods for time-series data and the availability of large volumes of sensor data, data-driven methods have gained popularity. Among the data-driven methods, timeseries foundation models (TSFMs), a class of deep-learning methods, especially, have proven to be effective on multi-variate time-series data. However, the deep-learning methods primarily addressed forecasting problems and do not explicitly consider different kinds of variates --- such as control and environment variables. In addition, these models being complex pose problems for control optimization, such as difficulty of obtaining gradients and sensitivities. In this talk, we outline effectiveness of TSFMs for process control, related challenges and solutions. Further, we demonstrate these solutions in the context of control optimization in industries such as cement manufacturing.

3 - Metric Learning-Based Semi-supervised Learning for Machinery Fault Diagnosis

Yunyoung Park, Incheon National University, Incheon, Korea, Republic of, Jaehong Yu

In recent years, deep neural network models have been successfully used for fault diagnosis of the machinery. Although the deep neural network-based models have properly worked under sufficient reliable label information on the operational status, those label information is often considerably insufficient in real situations due to expensive cost of labeling task. To address the label information insufficiency, deep semi-supervised learning methods have been proposed. However, existing deep semi-supervised learning methods might fail to achieve satisfactory performance in the fault diagnosis problem in that these methods suffers from inductive bias issues entailed with pseudo labeling procedure. For more superior fault diagnosis performance, in this study, we newly proposed a metric learning-based semi-supervised fault diagnosis method. The proposed model uses metric learning to extract more appropriate latent feature space where the signals having same label are close together, vice versa for different labels are far apart as possible. By doing so, the pseudo labeling outcomes gets more reliable, and it eventually improve the fault diagnosis performance. We conducted an experimental study using vibration signals obtained from a rolling element bearing simulator, and the results confirmed that the superiority of the proposed framework for detecting rotating machinery faults.

4 - Matrix Representation of the Elementary Operations of Individual Devices and Job Sequence for Control Programming

Hyeon min Yoon, Pohang University of Science and Technology, Pohang, Korea, Republic of, Duck Young Kim

The conventional procedure for manufacturing control programming is to define control logic gates and statements using the pre-specified hardware I/O information for the job sequence corresponding to manufacturing process requirements. Iteratively defining, testing, and adjusting control logic is typically time-consuming, often leading to delays in manufacturing project implementation. Therefore, in this paper, we discuss how to efficiently define, optimize, and verify control logics by automating the control programming process. To achieve this, we first present a mathematical representation in the form of a computer-friendly control matrix of the elementary operations of individual devices, their precedence and logical relationships, and changes in sensor values for each operation. A job sequence can then be represented as a series of matrix operations. We add extra entries to the control matrix as slack variables to calculate the state-transition results following the completion of each individual job. The proposed method is illustrated and validated with control logic programming for a robotized manufacturing workcell.

5 - Learning from Imbalanced Data with SMOTE-like Oversampling for Mixed Type and High Dimensional Data

Juhee Kim, Ewha Womans University, Seoul, Korea, Republic of, Dongil Kim

The class imbalance problem refers to the number of samples corresponding to each class in the data is not equal, which degrades model performances in machine learning tasks. To overcome this problem, various approaches have been studied, among which data-level resampling methods, including the Synthetic Minority Oversampling Technique (SMOTE) are widely used. The SMOTE and SMOTE-variants are successful oversampling algorithms to obtain balanced data for imbalanced data, but these methods still have difficulty in addressing class imbalance problems from different scenarios, such as the existence of class overlapping regions, high-dimensional data, and data with variables of mixed types. In this paper, we propose a novel oversampling algorithm for mixed type and high-dimensional data which performs re-sampling in a way that appropriately mitigates the problems of imbalanced data. The proposed method consists of four steps: grouping, selection, generation, and validation process. To avoid noisy sample generation in class overlapping region, the proposed method considers not only the information from each of the majority and minority classes, but also the relationship between classes. A new distance metric for both numerical and categorical variables is used throughout the process to allow for sample generation that better reflects the information in both categorical and numerical ones. Additionally, this method includes a verification procedure for the synthesized samples to ensure safe generation.

COPT/Responsive.net

Invited Session

Technology Showcase

1 - Unlocking Optimization Potential with COPT

Tiancheng Zhang, Cardinal Operations, Shanghai, China, People's Republic of

Join us for an insightful session on Cardinal Optimizer (COPT), where you'll discover its advanced and newly released capabilities for modeling and solving complex optimization problems. This presentation will introduce the current state of COPT and highlight new features, including a modeling interface for conic problems, support for the exponential cone, and first-order methods on GPU. Initial results on solving large-scale LPs on GPU show exciting possibilities to tackle previously unsolvable problems.

As the R&D team continues to achieve technical breakthroughs, our operations and support team are dedicated in engaging and enriching the COPT user community. With its user-friendly interfaces and comprehensive support, COPT has been seamlessly integrated into various packages and software for both research projects and industrial applications.

2 - Littlefield 2.0: A New Version of the Online Game for Operations Management Courses

Samuel Wood, Responsive Learning Techologies, Los Altos, CA, United States

After 25 years there is a new version of Littlefield! Littlefield is a competitive online simulation of either a factory or a medical laboratory that has been by more than half a million students in 500+ universities in 60+ countries to excite and engage students in operations management topics like process analysis and inventory control. This presentation will introduce a newly updated version 2 of the game that was released this past summer.

Advanced Bandit Algorithms and Optimization Techniques

Contributed Session

Chair: Kemal Gursoy, Rutgers University, 100 Rockafeller Road, Dept of MSIS, Room 5146, Piscataway, NJ, 08854, United States

1 - Multi-Armed Bandits and Games

Kemal Gursoy, Rutgers University, Piscataway, NJ, United States

A sequential optimization model, the multi-armed bandit problem, is concerned with optimal allocation of resources between competing activities, to generate the most likely benefits. In this work, following the objective of a multi-armed bandit problem, we consider a mean-field game theoretic model to approach to a large number of multi-armed bandits, and propose some connections between dynamic games and sequential optimization problems.

2 - A Multi-Task Deep Learning Approach to Large-Scale Lifetime Value Evaluation in Mobile Gaming Market

Qingpeng Zhang, The University of Hong Kong, Kowloon, Hong Kong, Mengzhuo Guo, Yijun Li, Binfeng Jia, Yang Liu

In the growing mobile gaming market, monetization tactics that encourage high-value transactions depend on the accurate and granular evaluation of user lifetime value (LTV). Existing probabilistic methods cannot handle multiple types of high-dimensional data with heavy-tailed distributions of in-game purchase amounts. Existing deep learning methods, on the other hand, do not account for the user heterogeneity across different mobile games. This study proposes an end-to-end deep multi-task learning approach for LTV prediction based on the Fogg Behavior model (FBM). It models the user's motivation and ability to pay as the probability and expectation of payment amount, respectively, and considers the co-effect of multiple mobile games. Besides achieving state-of-the-art performance in offline experiments, it also provides explainable results for analyzing user heterogeneity by examining their motivation and ability. We conducted large-scale field experiments on a real online advertising platform, showing that the proposed approach increased advertisers' Return on Investment by an average of 0.469\% for every 1\% improvement in the LTV prediction performance. Our approach is now deployed online, impacting billions of traffic daily.

3 - DISTRIBUTIONALLY ROBUST TWIN SUPPORT VECTOR MACHINE

Lesheng Wang, North Carolina State University, Raleigh, NC, United States, Fengming Lin, Shu-Cherng Fang, Xinyu Xu

In this presentation, we propose a distributionally robust twin support vector machine model to address the classification problems with uncertainty using the first and second-order information. The proposed model finds two nonparallel linear separation hyperplanes by solving two interconnected chance-constrained SVM models. Tractable SDP and SOCP reformulations are derived for efficient computations. Computational results on synthetic data and real-world benchmarks showcase superior performance of the proposed model compared with other established classification models, particularly for imbalanced datasets.

4 - Critical Analysis on Bio Inspired Optimization Methods and its Applications

Amit Kumar Saha, University of Arkansas, Fayetteville, AR, United States, Haitao Liao

In contemporary times, optimization techniques have evolved significantly in computing and complex problem-solving. Real-world problem formulation requires tuning various system parameters to achieve the best results within limited resources using diverse optimization methods. Traditional optimization techniques often rely on specific mathematical approaches tailored to applications. Recently, bio-inspired optimization has gained popularity due to its foundation in the practical behaviors of biological systems, which inherently seek optimal solutions to maintain systemic balance. When the design surface is non-linear, these optimization methods are very effective to finding the best solution. Numerous studies over the past few years have explored techniques that emulate these biological behaviors. This paper reviews the development, classification, performance and functioning of several prominent bio-inspired methods, highlighting their applications to real-world problems. It also identifies the gaps between theoretical foundations and practical applications of these techniques, suggesting directions for future research.

Advances in Causal Inference and Predictive Analytics

Contributed Session

Chair: Hossein Tohidi, SAS, 4131 Briargrove Circle, Apt 403, Raleigh, NC, 27607, United States

1 - Conformal Prediction for Interval Outcomes

Weiguang Liu, UCL, London, United Kingdom, Aureo de Paula, Elie Tamer

Interval censoring often occurs in economic data, leading to partial identification. Predicting outcomes that are interval censored is important in many practical scenario. We propose a new method to construct the prediction intervals for interval censored outcomes, by leveraging a natural characterisation of the sharp identified region of conditional cumulative distribution functions (CDF) rather than the conditional mean and the method of conformal inference. The proposed method is shown to both have finite-sample coverage guarantees and achieves asymptotic efficiency in terms of the volume of the prediction set.

2 - Confusion with the Confusion Matrix: a Meta-Analysis on Threshold Setting in Binary Classification

Patrick Moder, Kühne Logistics University, Hamburg, Germany, Kai Hoberg

Studies on binary classification usually report the balance of expected positive and negative outcomes (both true and false) to display classification model performance. Varying the decision threshold, which determines the cutoff between positive and negative classifications, calibrates that balance to maximize performance or minimize costs for expected misclassifications. In operations management, an optimal balance depends on study context and misclassification costs. The consequences of false alarms (false positive) can be less severe (costly) than missing a target (false negative), thus a certain balance of classifications is optimal. Yet, several studies do not reveal the rationale for calibrating classification outcomes. Hence, it is difficult to understand whether the results show a cost- or performance-optimizing solution, or an arbitrary (default) threshold was selected. When studies present their classification results in a confusion matrix or with relative metrics (precision and recall, e.g.), only outcomes for one particular decision threshold are shown. It is thus unclear how the performance varies at different thresholds and models can be operationalized. We conduct a meta-analysis on a large sample of research articles in operations management that present results of binary classifications and unveil how classifications are balanced. We describe used strategies to calibrate classifications, provide explanations for biased and boundedly rational calibration (anticipated regret or cry-wolf effect, e.g.), and provide recommendations for a rational and transparent reporting of classification performance. Our results have implications for researchers and practitioners who intend to rigorously report (with threshold-independent performance metrics, e.g.) or consciously interpret binary classification results.

3 - A Mixed Integer Programming Model for Designing Causal Inference Networks

Ali Ilhan Haliloglu, Bilkent University, Ankara, Turkey, Oya Ekin Karasan, Ozlem Karsu

In the realm of causal inference and probabilistic reasoning, understanding the relationships between variables is paramount. D-Separation and Connection, two fundamental concepts in the field of graphical models, provide a structured framework to determine whether variables are independent given a set of observed variables. D-Separation helps identify when variables are independent given certain observed variables, aiding in simplifying complex models. On the other hand, Connection highlights scenarios where variables are dependent, even when there is no direct link between them. Together, D-Separation and Connection offer invaluable insights into untangling the intricate web of causal relationships, enabling better decision-making and inference in diverse disciplines. Our research aims to write a mathematical model that will yield a graphical network with minimum weighted violations between dependent and independent variables with given collider sets. The weights of the relationships are determined with a known BIC test from the literature. The model uses a mixture of labeling and flow based modeling approach where variables are represented as nodes and edges represents the relationships between these variables. The model takes the dependence and independence relationships as parameters and the type of edges as decision variables and yields a network with minimum amount of weighted violation between variables.

4 - Graph-Based LogP Prediction: Leveraging Molecular Structure with Graph Neural Networks

Hossein Tohidi, SAS, Cary, NC, United States, Brandon Reese

Abstract:

Molecular structures can be effectively represented as graphs, with atoms as nodes and bonds as edges, offering rich connectivity patterns crucial for property prediction tasks. LogP, the logarithm of the partition coefficient, serves as a pivotal descriptor reflecting a molecule's hydrophobicity, influencing its behavior in biological processes and chemical environments. In this study, we propose a novel supervised approach that employs feature engineering and Graph Neural Networks (GNNs) to accurately predict LogP values from molecular graphs.

Our method exploits the inherent graph representation of molecules to systematically extract informative node- and graph-level features crucial for LogP prediction. Leveraging SAS Viya capabilities as well as the PyTorch Geometric Python package, we train our model on diverse datasets, ensuring robustness and generalization across various molecular structures. We conduct extensive experiments, benchmarking our approach against state-of-the-art methods in LogP prediction. Our results underscore the efficacy of our graph-based model in accurately predicting LogP values.

In summary, our work showcases the potential of Graph Neural Networks in elucidating graph properties for LogP prediction. By integrating graph representation learning with molecular property prediction, we offer a promising framework to enhance drug discovery and molecular design processes.

5 - Robust Bayesian Inference of Causal Effects via Randomization Distributions

Easton Huch, University of Michigan, Department of Statistics, Ann Arbor, MI, United States, Walter Dempsey, Fred Feinberg

We present a general framework for Bayesian inference of causal effects that delivers provably robust inferences based principally on the physical act of randomization. The framework involves fixing the observed potential outcomes and forming a simulation-based likelihood via the randomization distribution of a model-based discrepancy variable, a summary of the (imputed) complete data. We show posterior consistency of the method and derive theoretical connections to common estimators in causal inference. We illustrate the method and theoretical results in simulation and a case study.

Intersection of Machine Learning and Integer Programming

Invited Session

OPT: Integer and Discrete Optimization

Chair: Tengmu Hu, The Ohio State University, Columbus, OH, 43202, United States

Co-Chair: Tengmu Hu, The Ohio State University, Columbus, OH, 43202, United States

1 - An Integer Column Generation Algorithm for the Large Scale Optimal Classification Tree Problem

Tengmu Hu, The Ohio State University, Columbus, OH, United States

This paper explores the application of MIP techniques to enhance the efficiency of solving optimal classification tree problems. We introduce an exact integer column generation (ICG) algorithm and reformulate the problem as a set packing problem, leveraging its structural properties. Additionally, we investigate the convex hull of optimal classification tree formulations under tree depth equals to one. Both proposed pricing subproblems can be efficiently solved in polynomial time. Furthermore, we propose strategies for column addition and the generation of the next integer solution that yield maximal improvement.

2 - Learning to Disable Globally-Valid Cuts

Zixuan Feng, University of Florida, Gainesville, FL, United States

Cutting planes, or cuts, are a relaxation tightening technique employed by Mixed-Integer Programming (MIP) solvers, due to the fact it improves the average solving time. However, this is not always the case. For some instances, adding cuts can actually slow down the solving process for reasons including but not limited to the inequalities created are too dense, or too many cuts are added. Our research focuses on the Branch-and-Cut (B&C) method and aims to predict whether a MIP problem will benefit from disabling globally-valid cuts with the help of Machine Learning (ML) methods. Additionally, we tested different timings for making such a decision. Our study is tested with the MIPLIB 2017 benchmark dataset and showed promising results on improving the solving time by making adaptive choices.

3 - Learning to Branch in AC-Network Constrained Unit Commitment Problems

Selin Bayramoglu, Georgia Institute of Technology, Atlanta, GA, United States, George Nemhauser, Nikolaos Sahinidis

Unit commitment (UC) problems are challenging problems that power system operators solve multiple times a day. These problems are similar, differing only in some of the problem data involved, such as demands (loads). This work develops a machine-learning methodology to build a model that predicts strong branching scores—a costly expert branching rule—to speed up the solution of UC problems. The UC formulation in this study contains nonconvex AC power flow constraints and is thus a nonconvex mixed-integer nonlinear programming problem. This work shows that the SCIP solver equipped with the learned branching rule is faster than its default.

4 - Sample Complexity of Learning Cut Generating Functions

Hongyu Cheng, Johns Hopkins University, Baltimore, MD, United States, Amitabh Basu

Selecting an effective cutting plane to minimize the branch-and-cut tree size is a critical challenge in the branch-and-cut algorithm. Recent advancements have employed a data-driven approach to select optimal cutting planes from a parameterized family, aimed at reducing the branch-and-bound tree size for a given distribution of integer programming instances. We extend this idea to the selection of the best cut generating function (CGF) from a parameterized family of facet-defining valid functions for the infinite group relaxation problem, with Gomory's mixed-integer (GMI) cuts as a particular instance. We provide rigorous sample complexity bounds for the selection of an effective CGF from these families for any specified distribution under some mild assumptions. Our empirical results show that the selected CGF can outperform the GMI cuts for certain synthetic distributions. Additionally, we explore the sample complexity of using neural networks for instance-dependent CGF selection.

ONR Optimization Program Review: Applied Models and Algorithms

Invited Session

OPT: Computational Optimization and Software

Chair: David Phillips, Office of Naval Research, University of New Mexico, Catonsville, MD, United States

1 - New Perspectives on Critical Elements Detection in Complex Networks

Jourdain Lamperski, University of Pittsburgh, Pittsburgh, PA, United States, Oleg Prokopyev

Assessing a complex network’s vulnerability and quantifying its robustness properties with respect to adversarial attacks, natural disasters, and random failures is an important research question that arises in a variety of applications in telecommunication, transportation, social science, energy, and homeland security. This research challenge is often addressed using the graph-theoretic notion of critical elements, namely a subset of elements in a graph that satisfy some budget and/or structural constraints and whose removal (by some decision-maker) maximally degrades some desirable properties of the graph (e.g., its connectivity). Existing models typically use overly simplistic graph-theoretic notions as objective functions (e.g., the number of connected node pairs). The goal of part of our project is to consider more complex objective functions that build upon a rich body of related work in the network analysis literature. In this talk we will summarize results in this direction, specifically related to algebraic connectivity, a spectral graph measure that is often used to study robustness and synchronization properties of networks. The primary focus will be on approximation algorithms, but we will also discuss hardness results as well as exact algorithms based on combinatorial optimization formulations.

2 - Stochastic Programming Under Endogenous Uncertainty: Electric Vehicle Fleet for Energy Network Resilience

Miguel Lejeune, George Washington University, Washington, DC, United States, Payman Dehghanian

We propose new chance-constrained optimization models with decision-dependent uncertainty for the routing and scheduling of a fleet of electric vehicles used for enhancing energy network resilience and restoring service. Decisions pertaining to the assignment, dispatch, and coordination of the electric vehicle fleet and repair crews must be taken. The proposed models account for the coupling and interdependence between energy (power transmission and distribution) and transportation (ground and railway) networks under exogenous and endogenous uncertainties. We develop a solution approach that interlaces several reformulation and algorithmic methods. In general, the reformulated problems take the form of non-convex mixed-integer nonlinear problems. The algorithmic framework features optimality-based bound tightening methods and a specialized nonlinear branch-and-bound.

3 - An Overview of Optimizing Network Navigation in Stochastic Obstacle Scene Problem

Elvan Ceyhan, Auburn University, Auburn, AL, United States

This research focuses on optimizing navigation in networks with obstacles to address the stochastic obstacle scene (SOS) problem. This study examines two variants: the Optimal Traversal Path (OTP) problem and the Optimal Obstacle Placement (OOP) problem. The OTP problem involves a single navigating agent (NAVA) selecting a cost-minimal path through a space containing ‘forbidden region’. The OOP problem, recently introduced by the investigator, involves an obstacle-placing agent (OPA) strategically inserting obstacles to maximize the traversal length of the NAVA. The main goals are to improve heuristic algorithms for both SOS variants, introduce new strategies, extend the SOS problem to higher dimensions, develop weight-constrained versions of both variants, and analyze the theoretical properties and complexities of the algorithms. The application areas include defense logistics, autonomous path planning, target tracking, and supply chain management.

Keywords: Canadian traveler’s problem, spatial randomness, spatial pattern, network traversal and blocking, heuristic algorithm; stochastic ordering, adversarial agents, algorithm complexity

Joint work with Polat Charyyev, MAP Akademi, Istanbul, Turkey and Li Zhou, Auburn University, AL, USA

4 - Navy Vehicle Scheduling: Problem Formulation and Solutions

Sungjin Im, University of California, Merced, Merced, CA, United States, Mugen Blue, Benjamin Moseley, Rudy Zhou

The Navy operates a large number of vehicles. Scheduling these deployments presents a complex problem due to the critical nature of both the valuable hardware and the crew. These challenges are further exacerbated by various non-standard and non-trivial constraints. For example, vehicle operations must be accompanied by sufficient homeport training to ensure both deployment readiness and the long-term well-being of the crew.

In this talk, we will present the scheduling problems and challenges faced by the Navy, discuss how we model them, and explore how our model addresses these challenges.

Summit - 422

Large Language Models and Optimization

Invited Session

OPT: Machine Learning

Chair: Can Li, Purdue University, West Lafayette, IN, United States

1 - Ai and the Future of Optimization Modeling

Madeleine Udell, Stanford University, Stanford, CA, United States, Ali AhmadiTeshnizi, Wenzhi Gao

Optimization problems are pervasive in sectors from manufacturing and distribution to healthcare. However, most such problems are still solved heuristically by hand rather than optimally by state-of-the-art solvers, as the expertise required to formulate and solve these problems limits the widespread adoption of optimization tools and techniques.

As a glimpse of the future, this talk will introduce OptiMUS, a Large Language Model (LLM)-based agent designed to formulate and solve MILP problems from natural language descriptions. OptiMUS can develop mathematical models, write and debug solver code, develop tests, and check the validity of generated solutions. Experimentally, OptiMUS correctly solves more than 80% of benchmark problems, more than twice as many as a basic LLM prompting strategy. More broadly, we discuss the potential for LLMs in domains where accuracy and fidelity to real-world data is critical and strategies to augment and safeguard their performance.

2 - Synthesizing Mixed-Integer Linear Programming Models from Natural Language Descriptions

Qingyang Li, The University of Melbourne, Melbourne, Australia, Lele Zhang, Vicky Mak-Hau

Numerous real-life problems arising in various domains can be formulated and solved using Mixed-Integer Linear Programming (MILP) models. However, the transformation of real-world decision-making problems into MILP models requires expertise in Operations Research and mathematical optimization, which restricts non-experts' accessibility to MILP. To address this challenge, we propose a framework for automatically formulating MILP models from unstructured natural language descriptions of decision problems, which integrates Large Language Models (LLMs) and mathematical modeling techniques. This framework consists of three phases: i) identification of decision variables, ii) classification of objective and constraints, and iii) generation of MILP models.

In this study, we propose a knowledge representation structure that includes relational knowledge and inheritable knowledge. Specifically, we present a constraint classification scheme and a set of constraint templates that can guide the LLMs in synthesizing a complete MILP model from natural language. Our approach can synthesize logic constraints and classic demand and resource constraints.

To assess our framework, we extend the NL4Opt dataset with more constraint types, and create a new test dataset. With respect to the accuracies of generating the correct model, objective, and constraints, our method which integrates knowledge representation with LLMs significantly outperforms one-step model generation methods offered by ChatGPT and Google Bard. Our three-phase prototype system for automatically formulating MILP models has a great potential to capture more types of constraints for more complex problems. It opens up opportunities for developing training tools for operations research practitioners and powerful tools for automatic decision problem modeling and solving in practice.

3 - "I Want It that Way": Enabling Interactive Decision Support via Large Language Models and Constraint Programming

Connor Lawless, Cornell University, Ithaca, NY, United States

Mathematical Programming has been a transformative technology for improving decision making in a number of industrial applications but its impact has been largely realized by large institutions that can afford the optimization expertise. We present a novel framework for interactive decision support for non-expert users that leverages large language models (LLM) to translate natural language requests into operations on an underlying constraint programming model. We study this hybrid framework through the lens of meeting scheduling, a time-consuming daily activity faced by a multitude of information workers. We conduct three studies to evaluate the novel framework, including a diary study (n=64) to characterize contextual scheduling preferences, a quantitative evaluation of the system's performance, and a user study (n=10) with a prototype system. Our work highlights the potential for a hybrid LLM and optimization approach for iterative preference elicitation and design considerations for building systems that support human-system collaborative decision-making processes.

4 - Explaining Optimization Models Using LLMs

Can Li, Purdue University, West Lafayette, IN, United States, Hao Chen, Gonzalo Constante Flores

We will present OptiChat, a chatbot for explaining optimization models through sensitivity analysis, infeasible diagnosis, and counterfactual explanation that is powerd by large language models.

Robust Optimization for Social Good

Invited Session

OPT: Optimization Under Uncertainty

Chair: Qing Jin, USC University of Southern California, LA, CA, United States

Co-Chair: Phebe Vayanos, University of Southern California, Los Angeles, CA, United States

1 - Robust Offline Policy Learning Under Covariate Shift

Bill Tang, University of Southern California, Los Angeles, CA, United States, Cagil Kocyigit, Phebe Vayanos

We study the problem of distribution shifts in offline policy learning, where
the policy training distribution is different from the deployment distribution and may lead to harmful or sub-optimal policy actions at deployment. In real world applications, changes to an allocation system can cause shifts in measured covariates, such as wording changes in survey questions that elicit different responses from individuals experiencing homelessness. As a result, a non-robust allocation policy may incorrectly over or under allocate resources based on the original offline data distribution. Motivated by this, we seek to learn an allocation policy that is not restricted to any functional form and robust to potential covariate shifts in the population of allocatees.

2 - Wasserstein Logistic Regression Robust to Distribution Shifts

Qingshi Sun, University of Southern California, Los Angeles, CA, United States, Nathan Justin, Andres Gomez, Phebe Vayanos

Logistic regression is one of the most popular classification models in high-stakes domains due to its great interpretability. Also, in high-stakes domains, data tend to be collected by surveys that are sensitive to many factors, such as the level of comfort respondents have in providing information, when and where the survey is conducted. These factors may affect the data collection and lead to shifts in data distribution. Therefore, we propose a distributionally robust logistic regression model robust to distribution shifts. Compared to recent work, our model includes all kinds of features (i.e., numerical, integer, and categorical) and thus significantly extends the fields of application. Also, the model includes the likelihood of the perturbation of each feature. We evaluate the performance of our model on numerous publicly available datasets, and compare the performance to a regularized logistic regression. Our proposed model achieves improvement in calibration error and the area under the ROC curve (AUC). Despite the distributionally robust model amounting to an exponential-size optimization problem, we reformulate the model equivalently by combining the shortest path problem based on dynamic programming digraphs. This allows the reformulated model to be solved by an off-the-shelf solver in polynomial time.

3 - Learning Optimal Classification Trees Robust to Distribution Shifts

Nathan Justin, University of Southern California, Los Angeles, CA, United States, sina Aghaei, Andres Gomez, Phebe Vayanos

We consider the problem of learning classification trees that are robust to distribution shifts between training and testing/deployment data. This problem arises frequently in high stakes settings such as public health and social work where data is often collected using self-reported surveys which are highly sensitive to e.g., the framing of the questions, the time when and place where the survey is conducted, and the level of comfort the interviewee has in sharing information with the interviewer. We propose a method for learning optimal robust classification trees based on mixed-integer robust optimization technology. In particular, we demonstrate that the problem of learning an optimal robust tree can be cast as a single-stage mixed-integer robust optimization problem with a highly nonlinear and discontinuous objective. We reformulate this problem equivalently as a two-stage linear robust optimization problem for which we devise a tailored solution procedure based on constraint generation. We evaluate the performance of our approach on numerous publicly available datasets, and compare the performance to a regularized, non-robust optimal tree. We show an increase of up to 12.48% in worst-case accuracy and of up to 4.85% in average-case accuracy across several datasets and distribution shifts from using our robust solution in comparison to the non-robust one.

4 - Biodiversity Conservation via Adjustable Robust Optimization

Qing Jin, University of Southern California, LA, CA, United States, Yingxiao Ye, Christopher Doehring, Angelos Georghiou, Hugh Robinson, Phebe Vayanos

Human development is a threat to biodiversity and conservation organizations (COs) are purchasing land to protect areas for biodiversity preservation. COs have limited budgets and cannot purchase all the land necessary to perfectly preserve biodiversity, and human activities are uncertain, so exact developments are unpredictable. We propose a multistage, robust optimization problem with a data-driven hierarchical-structured uncertainty set which captures the endogenous nature of the binary (0-1) human land use uncertain parameters to help COs choose land parcels to purchase to minimize human impact on biodiversity. We simulate the development based on climate data, land characteristics, and human land use data. We use the simulation to build data-driven uncertainty sets. We demonstrate that an equivalent formulation of the problem can be obtained that presents exogenous uncertainty only and where uncertain parameters only appear in the objective. We leverage this reformulation to propose a conservative approximation and showcase the proposed approach outperform the existing methods widely used in the biodiversity conservation community.

5 - Mistake, Manipulation and Margin Guarantees in Online Strategic Classification

Lingqing Shen, Carnegie Mellon University, Pittsburgh, PA, United States, Nam Ho-Nguyen, Khanh-Hung Giang-Tran, Fatma Kilinc-Karzan

We consider an online strategic classification problem where each arriving agent can manipulate their true feature vector to obtain a positive predicted label, while incurring a cost that depends on the amount of manipulation. The learner seeks to predict the agent's true label given access to only the manipulated features. After the learner releases their prediction, the agent's true label is revealed. Previous algorithms such as the strategic perceptron guarantee finitely many mistakes under a margin assumption on agents' true feature vectors. However, these are not guaranteed to encourage agents to be truthful. Promoting truthfulness is intimately linked to obtaining adequate margin on the predictions, thus we provide two new algorithms aimed at recovering the maximum margin classifier in the presence of strategic agent behavior. We prove convergence, finite mistake and finite manipulation guarantees for a variety of agent cost structures. We also provide generalized versions of the strategic perceptron with mistake guarantees for different costs. Our numerical study on real and synthetic data demonstrates that the new algorithms outperform previous ones in terms of margin, number of manipulation and number of mistakes.

Summit - 424

Algorithms for Robust Optimization

Invited Session

OPT: Optimization Under Uncertainty

Chair: Kartikey Sharma, Zuse Institute Berlin, Berlin, Germany

1 - Tractable Optimization Under Multilinear Uncertainty

Kartikey Sharma, Zuse Institute Berlin, Berlin, Germany, Eojin Han, Omid Nohadani

Capturing the endogeneity of uncertainity can lead to non-linear models. However, most research on optimization under uncertainty has focused on linear settings. We develop reformulation techniques for Robust and Distributionally Robust Optimization to tackle uncertainties which affect the optimization problem through a multilinear function. For RO, we provide a general conservative reformulation and provide situations in which the reformulation is exact whereas for DRO we show that for particular ambiguity sets the problem can be reformulated as a stochastic program. These techniques lead to efficient algorithms to solve problems with recursive uncertainties such as balking.

2 - A Nonparametric Approach with Marginals for Modeling Consumer Choice

Yanqiu Ruan, Singapore University of Technology and Design, Singapore, Singapore, Xiaobo Li, Karthyek Murthy, Karthik Natarajan

Given data on the choices made by consumers for different offer sets, a key challenge is to develop parsimonious models that describe and predict consumer choice behavior while being amenable to prescriptive tasks such as pricing and assortment optimization. The marginal distribution model (MDM) is one such model, which requires only the specification of marginal distributions of the random utilities. This paper aims to establish necessary and sufficient conditions for given choice data to be consistent with the MDM hypothesis, inspired by the utility of similar characterizations for the random utility model (RUM). This endeavor leads to an exact characterization of the set of choice probabilities that the MDM can represent. Verifying the consistency of choice data with this characterization is equivalent to solving a polynomial-sized linear program. Since the analogous verification task for RUM is computationally intractable and neither of these models subsumes the other, MDM is helpful in striking a balance between tractability and representational power. The characterization is convenient to be used with robust optimization for making data-driven sales and revenue predictions for new unseen assortments. When the choice data lacks consistency with the MDM hypothesis, finding the best-fitting MDM choice probabilities reduces to solving a mixed integer convex program. Numerical experiments show that MDM provides better representational power and prediction accuracy than multinominal logit and significantly better computational performance than RUM.

3 - Primal-Dual Algorithms for Stochastic Distributionally Robust Optimization

Zaid Harchaoui, University of Washington, Seattle, WA, United States

We consider the penalized distributionally robust optimization (DRO) problem with a closed, convex uncertainty set, a setting that encompasses the f-DRO, Wasserstein-DRO, and spectral/L-risk formulations used in practice. We present Drago, a stochastic primal-dual algorithm that achieves a state-of-the-art linear convergence rate on strongly convex-strongly concave DRO problems. The method combines both randomized and cyclic components with mini-batching, which effectively handles the unique asymmetric nature of the primal and dual problems in DRO. We support our theoretical results with numerical benchmarks in classification and regression. This is joint work with Ronak Mehta and Jelena Diakonikolas.

4 - Distributed Robust Optimization for Multi-Agent Robotic Systems

Evangelos Theodorou, Georgia Institute of Technology, Atlanta, GA, United States

For multi-agent autonomous robotic systems to successfully perform challenging tasks, they must robustly operate in dynamic and uncertain environments. While there has been a plethora of prior work on distributed decision-making, there are no scalable algorithms that can handle different types of uncertainty. Decision-making algorithms based on robust optimization have the capability to handle deterministic and stochastic uncertainties. However, this capability comes at the price of high computational cost which prohibits the applicability of robust optimization to large-scale multi-agent robotics systems. In this talk we present a scalable distributed robust optimization framework that addresses these issues. The proposed approach can handle different types of uncertainties while retains computational efficiency. The presentation includes tractable approximations of robust constraints that are relevant to multi-robot settings as well as a complexity analysis. Several examples and use cases on multi-agent robotic navigation tasks will be presented to demonstrate the scalability and efficacy of the proposed distributed robust trajectory optimization framework. Finally, future directions on the theory and applications will be discussed.

First-order Methods in Continuous and Stochastic Optimization

Invited Session

OPT: Nonlinear Optimization

Chair: Jiaming Liang, University of Rochester, Rochester, NY, United States

1 - a Simple Uniformly Optimal Method Without Line Search for Convex Optimization

Tianjiao Li, Georgia Institute of Technology, Atlanta, GA, United States, Guanghui Lan

Line search (or backtracking) procedures have been widely employed into first-order methods for solving convex optimization problems, especially those with unknown problem parameters (e.g., Lipschitz constant). In this paper, we show that line search is superfluous in attaining the optimal rate of convergence for solving a convex optimization problem whose parameters are not given a priori. In particular, we present a novel accelerated gradient descent type algorithm called auto-conditioned fast gradient method (AC-FGM) that can achieve an optimal O(1/k^2) rate of convergence for smooth convex optimization without requiring the estimate of a global Lipschitz constant or the employment of line search procedures. We then extend AC-FGM to solve convex optimization problems with Holder continuous gradients and show that it automatically achieves the optimal rates of convergence uniformly for all problem classes with the desired accuracy of the solution as the only input. Finally, we report some encouraging numerical results that demonstrate the advantages of AC-FGM over the previously developed parameter-free methods for convex optimization.

2 - Tangent Subspace Descent via Discontinuous Subspace Selections on Fixed-Rank Manifolds

David Gutman, Texas A&M University, College Station, TX, United States, Nam Ho-Nguyen, Daniel Grady

The tangent subspace descent method (TSD) extends the coordinate descent algorithm to manifold domains. The key insight underlying TSD is to draw an analogy between coordinate blocks in Euclidean space and tangent subspaces of a manifold. The core principle behind ensuring convergence of TSD for smooth functions is the appropriate choice of subspace at each iteration. Previously, it was shown that it is always possible to appropriately pick such subspaces on the broad class of manifolds known as naturally reductive homogeneous spaces. In this talk, we provide the first instances of TSD for manifolds outside of this class. The main idea underlying these new instances is the use of discontinuous subspace selections. As a result of our developments we derive new and efficient methods for large-scale optimization on the fixed-rank and fixed-rank positive semidefinite matrix manifolds.

3 - A Nearly Linearly Convergent First-Order Method for "Typical" Nonsmooth Functions

Liwei Jiang, Georgia Institute of Technology, Atlanta, GA, United States

Nonsmooth optimization problems appear throughout machine learning and signal processing. Standard gradient methods in nonsmooth optimization are often described as “slow” since the well-known “lower-complexity bounds” suggest they converge at best sublinearly. In this talk, I will introduce a first-order method that (locally) exponentially improves upon such lower bounds. The method is “parameter-free” and converges nearly linearly on “typical” optimization problems. The key insight is that “typical” nonsmooth functions are not pathological but are “partially smooth” in algorithmically useful ways.

4 - Accelerated Optimization over Smooth and/OR Strongly Convex Sets

Benjamin Grimmer, Johns Hopkins University, Baltimore, MD, United States

We consider feasibility and constrained optimization problems defined over smooth and/or strongly convex sets. These notions mirror their popular function counterparts but are much less explored in the first-order optimization literature. In this talk, we will aim to lessen this gap.

We first extend the computer-assisted performance estimation problem machinery to such problems. From this, we derive new and improved theory for classic methods like Frank-Wolfe and alternating projections directly benefiting from smoothness and strong convexity of constraint sets. Considering new gauge-based methods, we derive optimal accelerated convergence guarantees of O(1/T) for problems with strongly convex constraint sets and O(1/T^2) for smooth constraint sets. This second analysis are based on novel characterizations of the Minkowski gauge of smooth and/or strongly convex sets, which may be of independent interest: although the gauge is neither smooth nor strongly convex, we show the gauge squared inherits any structure present in the set.

1 - Machine Learning-Augmented Optimization of Large Bilevel and Two-Stage Stochastic Programs: Application to Cycling Network Design

Bo Lin, University of Toronto, North York, ON, Canada

Motivated by a cycling infrastructure planning application, we present a machine learning approach to solving bilevel programs with a large number of independent followers, which as a special case includes two-stage stochastic programming. We propose an optimization model that explicitly considers a sampled subset of followers and exploits a machine learning model to estimate the objective values of unsampled followers. Unlike existing approaches, we embed machine learning model training into the optimization problem, which allows us to employ follower features that cannot be represented using leader decisions. We prove bounds on the optimality gap of the generated leader decision as measured by the original objective that considers the full follower set. We develop follower sampling algorithms to tighten the bounds and a representation learning approach to learn follower features, which are used as inputs to our machine learning model. Through numerical studies, we show that our approach generates leader decisions of higher quality compared to baselines. Finally, we perform a real-world case study in Toronto, Canada, where we solve a cycling network design problem with over one million followers. Compared to the current practice, our approach improves a transportation metric by 19.2% and can lead to a potential cost saving of $18M.

2 - Balancing Fairness and Efficiency in Traffic Routing via Interpolated Traffic Assignment

Devansh Jalota, Stanford University, Stanford, CA, United States

System optimum (SO) routing, wherein the total travel time of all users is minimized, is a holy grail for transportation authorities. However, SO routing may discriminate against users who incur much larger travel times than others to achieve high system efficiency, i.e., low total travel times. To address the inherent unfairness of SO routing, we study a fairness constrained traffic assignment problem which minimizes the total travel time while achieving a desired fairness level specified by the maximum ratio between the travel times of users with shared origins and destinations. To obtain feasible solutions to this problem while achieving high system efficiency, we develop a new convex program, the interpolated traffic assignment problem (I-TAP), which interpolates between a fairness-promoting and an efficiency-promoting traffic-assignment objective. We evaluate the efficacy of I-TAP through theoretical bounds on the total system travel time and level of fairness in terms of its interpolation parameter and present a numerical comparison between I-TAP and a state-of-the-art algorithm. The numerical results indicate that our approach is faster by several orders of magnitude compared to the benchmark, while achieving higher system efficiency for all desirable fairness levels. We further leverage I-TAP's structure to develop pricing mechanisms to collectively enforce the I-TAP solution in the presence of selfish users that independently choose routes to minimize their travel costs. We mention that this is the first study of pricing in the context of fair routing for general road networks (as opposed to, e.g., parallel networks).

3 - Fair Fares for Vehicle Sharing Systems

Hyemi Kim, Columbia University, New York, NY, United States

Vehicle sharing systems, like those for bicycles, scooters, and cars, have become essential transportation options, with fares often set by companies through mobile apps. This can result in users in different locations paying varying prices and experiencing unequal access. Platforms and regulatory bodies should consider how to set prices fairly to minimize the inequalities experienced by users across locations, for which we provide a framework and insights in this work. We consider two notions of fairness corresponding to price and access. Price fairness is a measure of how close the prices at two locations are to one another. Access fairness compares the fraction of demand at each location that has access to the system, where access is a product of affordability and vehicle availability. We analyze the impact of imposing these fairness measures on the revenue, consumer surplus, and social welfare using a stylized model with two locations. Under price fairness, we analytically identify regimes where consumer surplus at both locations can increase or can both decrease. We show that access fairness decreases consumer surplus at both locations, making all parties worse off. To address the non-convexity in generalized networks with multiple locations and vehicles, we design a sliding window method for price fairness and employ a convex relaxation technique achieving asymptotic optimality for access fairness. Lastly, a case study using real-word data of a vehicle sharing system operating in New York City shows that a significant gain in fairness can be achieved with a relatively small loss in revenue

4 - Subpath-Based Column Generation for the Electric Routing-Scheduling Problem

Sean Lo, Massachusetts Institute of Technology, Cambridge, MA, United States

Motivated by widespread electrification targets, this paper studies an electric routing-scheduling problem (ERSP) that jointly optimizes routing-scheduling and charging decisions. The ERSP is formulated as a semi-infinite set-partitioning model, where continuous charging decisions result in infinitely-many path-based variables. To solve it, we develop a column generation algorithm with a bi-level label-setting algorithm to decompose the pricing problem into (i) a first-level procedure to generate subpaths between charging stations, and (ii) a second-level procedure to combine subpaths into paths. We formalize subpath-based domination properties to establish the finite convergence and exactness of the column generation algorithm. We prove that the methodology can handle modeling extensions with heterogeneous charging costs (via dynamic re-optimization of charging decisions) and algorithm extensions to tighten the relaxation using ng-routes and limited-memory subset-row inequalities (via augmented domination criteria). Computational results show that the methodology scales to large instances, outperforming state-of-the-art column generation algorithms. From a practical standpoint, the methodology achieves significant cost reductions by jointly optimizing routing-scheduling and charging decisions and by capturing heterogeneous charging costs.

Planning and Operations for Shared Mobility

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Kai Wang, Tsinghua University, Beijing, 100084

Co-Chair: Alexandre Jacquillat, MIT Sloan School of Management, Cambridge, MA, United States

1 - From Lab to Real World : Understanding the Practical Complexities of Decision Making for On Demand Transit Systems

Abhishek Dubey, Vanderbilt University, Nashville, TN, United States, Sophie Pavia, Aron Laszka, Ayan Mukhopadhyay, Samitha Samaranayake

While on-demand ride-sharing services have become popular in recent years, traditional on-demand transit services cannot be used by everyone, e.g., wheelchair-bound people. Paratransit services, operated by public transit agencies, are a critical infrastructure that offers door-to-door transportation assistance for individuals who face challenges in using standard transit routes. However, with declining ridership and mounting financial pressure, public transit agencies in the USA struggle to operate existing services. We collaborate with a public transit agency from the southern USA, highlight the specific nuances of paratransit optimization, and present a vehicle routing problem formulation for optimizing paratransit. We validate our approach using real-world data from the transit agency, present results from an actual pilot deployment of the proposed approach in the city, and show how the proposed approach comprehensively outperforms existing approaches used by the transit agency. We present a customizable, open-source algorithmic approach for paratransit optimization that allows for hard domain-specific constraints to be captured.

2 - Dynamic capacity planning for demand-responsive multimodal transit

Bernardo Martin-Iradi, ETH Zurich, Zürich, Switzerland, Kayla Cummings, Alexandre Jacquillat, Alexandria Schmid

Microtransit offers opportunities to enhance urban mobility by combining the reliability of public transit and the flexibility of ride-sharing. This paper optimizes the design and operations of a deviated fixed-route microtransit system that relies on reference lines but is allowed to deviate in response to passenger demand. We formulate a Microtransit Network Design (MiND) model via two-stage stochastic optimization. The model features a tight second-stage formulation thanks to a subpath-based representation of microtransit operations in a load-expanded network, which optimizes on-demand deviations between checkpoint stops. We develop a double-decomposition algorithm combining Benders decomposition and subpath-based column generation armed with a tailored label-setting algorithm. Using real-world data from

Manhattan, results suggest that our method scales to large practical instances, with up to 10-100 candidate lines and hundreds of stations. Comparisons with transit and ride-sharing benchmarks suggest that microtransit can provide win-win outcomes toward efficient mobility (high demand coverage, low operating costs, high level of service), equitable mobility (broad geographic reach) and sustainable mobility (limited environmental footprint). We provide an open-source implementation in an online repository to enable replication.

3 - Optimizing Relay Operations Toward Sustainable Logistics

Alexandria Schmid, MIT Operations Research Center, Cambridge, MA, United States, Alexandre Jacquillat, Kai Wang

Relay logistics decompose long-haul shipments into short segments through a pit-stop network, traveled by separate drivers. This paper develops optimization models, scalable algorithms and actionable insights to support and assess relay operations. A theoretical model highlights that relays can jointly improve drivers' working conditions, delivery speeds and distances traveled by smoothing out demand variability along high-volume pit-stop corridors. Next, we formulate a mixed-integer optimization model optimizes and coordinates the routing of orders, drivers and vehicles in large-scale relay logistics networks. To solve it, a multi-arc generation algorithm iteratively adds arcs to time-space networks by seeking a path of negative reduced cost within a relaxed and projected polyhedron. Extensive data-driven results show that (i) the algorithm outperforms state-of-the-art benchmarks and scales to large and practical instances; (ii) the optimization methodology can yield significant gains in relay logistics; and (iii) relay can provide benefits as compared to point-to-point operations, consistently with our theoretical findings. With our optimization methodology, relay operations can ultimately provide win-win-win outcomes in logistics toward the ``3 E's'' of sustainability: equity (working conditions), economy (delivery lead times, operating costs), and environmental footprint.

4 - Value of Sharing in Robots-as-a-service Operations

Kai Wang, Tsinghua University, Beijing, China, People's Republic of

``Robots-as-a-Service'' (RaaS) is an emerging operating model that promotes automation adoption through sharing. For example, FarmWise, a leader in robotics for agriculture, operates a fleet of weeding robots that serve many geographically dispersed users. Such RaaS platforms allocate robotic assets to users (a routing-scheduling problem) and assign tasks to these robots (a workload planning problem). This paper develops optimization models, practical insights, and scalable algorithms to support these decisions. First, a theoretical model analyzes the interplay between routing optimization and workload balancing. It emphasizes the two-sided value of sharing, i.e., the value of sharing robots across users, sharing workload across robots, and the necessity to combine both to achieve the best of both worlds. Next, this paper presents a mixed-integer optimization model to facilitate RaaS operations in practice. To solve this model efficiently, we develop an ``explore-and-bound'' algorithm that iterates between a restricted master problem and a convexity-based relaxation, while iteratively adding ``exploration cuts'' to visit new solutions. Computational results demonstrate that this methodology yields higher-quality solutions than several benchmarks and can scale to large and practical instances. By using data from FarmWise, we show that the proposed optimization approach can yield significant benefits, including a reduction in travel times (with environmental benefits) and overtime work (with social benefits), enabling a higher utilization of the robotic fleet.

Mathematical Innovations in Curb Space Management, Pricing, and Service Operations

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Jisoon Lim, University of Michigan, Ann Arbor, MI, United States

Co-Chair: Neda Masoud, University of Michigan Ann Arbor

1 - Spatiotemporal Pricing of Curb Space for Improving Operator and User Utilities

Jisoon Lim, University of Michigan, Ann Arbor, MI, United States

Effective curb space management emerges as a critical consideration within the revolutionary urban transportation system. Facilitating various transportation operations is contingent on appropriate allocation and pricing strategies for available curb spaces. We propose a Stackelberg game-theoretical model to illustrate the dynamics of curb space operation accommodating diverse curb space usages, where the game leader operates the curb space by setting spatiotemporal pricing policy and space allocation for each curb space usage, and the multi-followers evaluate the policy by accepting or rejecting curb space participation. Applying spatiotemporal pricing allows the operator to adjust pricing strategies across different curb space zones in response to demand dynamics and allocation policies. We formalize this game as a bi-level nonlinear optimization problem and solve it using Lagrangian relaxation applied to a single-level reformulation model. Numerical experiments demonstrate the effectiveness of spatiotemporal pricing schemes in mutually benefitting curb space stakeholders and improving the game equilibrium. We further discuss integrating practical considerations to capture the intricacies of curb space user characteristics.

2 - The Effect of Dynamic AI Surge Pricing on Passengers’ Tipping Behavior in Ride-Hailing Service: An Empirical Evidence from Uber Platform

Xiaohui Liu, Department of Information Systems and Analytics, School of Computing, National University of Singapore, Singapore, Singapore, Yujing Ma, Liang Zhang, Wei Ma, Hock-Ha Teo

Tipping on the Uber platform not only exerts a considerable influence on the economic remuneration of drivers but also serves as a vital social lubricant to enhance drivers’ job motivation and satisfaction. Accompanying the Uber platform, the designed and adopted Artificial Intelligence (AI) surge pricing benefits the platform directly by increasing company revenue. However, its dynamics in adjusting trip fares also have the potential to diminish drivers' benefits by reducing the ratio of tips received from passengers. This study empirically investigates the externality of AI surge pricing on passengers' tipping behaviour on the Uber platform in New York City. Empowered by the two-stage least square (2SLS) econometric method, our empirical evidence demonstrates that the higher AI surge pricing adopted by the Uber platform will negatively affect the tipping ratio of passengers. A series of mechanism checks justify that passengers, as the payers for both dynamic AI surge pricing and voluntary tips, will tend to transform their algorithm aversion towards platforms into negative tipping behaviours towards drivers. Our findings imply that the company's profit-driven pricing strategy may not achieve a win-win situation by overlooking its indirect impact on drivers' rights. This study provides insights into labor management on ride-hailing platforms, particularly regarding safeguarding labor benefits amidst the prevalent adoption and use of AI surge pricing in ride-hailing services.

3 - Economic Analysis of on-Street Parking with Urban Delivery

Zhengtian Xu, The George Washington University, Washington, DC, United States, Xiaotong Sun

The surge in online shopping has dramatically increased the demand for short-term curb access for package pickups and deliveries, leading to heightened competition for limited curb space. This study addresses the problem of how the unique parking demand of deliverers, particularly their parking duration for delivery attempts linked to parking space availability, affects the dynamics of urban curb parking systems. We develop continuum models of a curb parking system and perform analytical analyses to understand the dynamics and steady-state properties of the system under the influence of increased urban deliveries. We conduct comparative statics to examine how various curb management measures, such as pricing, parking duration caps, and dedicated delivery bays, influence the equilibrium conditions, followed by comparisons of the theoretical capacity of these measures. The results suggest that pricing strategies for metered parking to general parkers prove to be more efficient and flexible compared to other interventions. Particularly, when curb parking pricing is optimally calibrated, the necessity for dedicated delivery bays diminishes. Our findings provide valuable insights into the distinct impact deliverers have on curb parking dynamics, highlighting the need for a strategic reevaluation of current management practices.

4 - Adaptive Parking Pricing using Graph Neural Networks

Fatemeh Sadeghi, York University, Toronto, ON, Canada

Like many cities, Toronto has limited parking availability and high demand, which makes searching for parking spaces cumbersome. Rather than spending considerable time in an almost fully occupied parking space near the desired destination, a less expensive but farther parking location within walking distance may be an alternative for drivers. To balance the demand and the supply of parking zones, this study proposes an adaptive pricing algorithm for on-street parking locations in close vicinity, i.e., increasing the parking cost in a crowded spot. An iterative optimization algorithm is introduced to determine the optimal price for individual parking locations. The number of occupied parking locations (NOPS) is estimated using the transaction data provided by the Toronto Parking Authority (TPA), which is financially efficient and easily accessible. The TPA data comprises arrival and departure times and dates during May, June, and July 2019 and 2022. The Graph Neural Network (GNN) is specifically trained by the TPA data to predict the NOPS after updating the price profile. Input features for each parking location are categorized into sociodemographic data from the City of Toronto and amenity data obtained from the Open Street Map. The GNN framework captures spatial relationships among parking locations. A linked-based algorithm is proposed for the adaptive pricing algorithms. It shows that, after 30 iterations of price increase, the number of unbalanced parking locations has decreased from 2189 to 2134 out of 2572 comparisons and the average occupancy rate has increased from 27% to 38%.

Summit - 430

Aircraft and Crew Planning

Invited Session

Aviation Applications

Chair: Pushpendra Singh, Dartmouth College, Hanover, NH, United States

1 - Anticipating uncertainty in flight planning and scheduling

M. Selim Akturk, Bilkent University, Ankara, Turkey

We introduce a new scheduling approach for the flight planning and scheduling problem. Our main focus is to anticipate possible disruptions of an aircraft due to its mechanical failures along with possible delays that might be caused by the congestions of a flight at the origin and destination airports. Consequently, we could minimize the high opportunity costs caused by the flight cancellations and passenger inconvenience caused by delays in the schedule. We show that by allowing a small deviation from the minimum cost schedule at the schedule generation phase, the potential recovery costs in the future can be reduced significantly.

2 - Assessment of maintenance slot policies for an aircraft fleet using Value of Information in a Condition-Based Maintenance environment

Iordanis Tseremoglou, Delft University of Technology-Faculty of Aerospace Engineering, The Hague, Netherlands, Dimitrios Zarouchas, Bruno F. Santos

Aircraft maintenance is pivotal for airline safety and profitability. Following advancements in sensor technology and prognostics, aircraft maintenance is transitioning from traditional preventive and corrective approaches to Condition-Based Maintenance (CBM). However, the accuracy and uncertainty of Remaining Useful Life (RUL) predictions present challenges for optimizing maintenance operations. Tailored slot policies are essential, with conservative policies for high-certainty predictions and more frequent slot policies for uncertain RUL predictions. In this context, optimizing CBM necessitates quantifying its benefits, asking "how much information is worth?" through Value of Information (VoI) analysis. This extends beyond accounting only for the component maintenance costs but also considering the costs of introducing extra maintenance slots. Integrating VoI into policy decisions allows airlines to evaluate trade-offs between sensor investments and slot practices. A novel approach is introduced to evaluate maintenance slot policies in a CBM environment, considering RUL predictions of varying accuracy and uncertainty levels. Historical airline data and the C-MAPSS dataset are used to simulate maintenance tasks and RUL predictions. A scheduling model using a Deep Reinforcement Learning algorithm calculates maintenance costs under traditional and prognostics-driven approaches, extracting VoI associated with integrating RUL predictions. Results show that VoI varies significantly based on accuracy, uncertainty, component costs, and slot policy. The conducted VoI analysis provides useful insights that can aid decision-makers in selecting appropriate slot policies aligned with RUL predictions accuracy and uncertainty. Overall, this research advances CBM optimization for aircraft fleets, offering practical insights for enhancing maintenance operations in the aviation industry.

3 - Tail Assignmet-Driven Aircraft Routing Problem

Rubén Jiménez Moreno, Rey Juan Carlos University, Fuenlabrada, Spain, Manuel Fuentes González, Luis Cadarso

Airline planning confronts complex optimization challenges due to limited data availability, addressing aircraft routing and tail assignment across various timeframes, from months to days before operations commence. Operational fluctuations like flight cancellations necessitate continuous updates to rotations and tail assignments, demanding a flexible approach for seamless planning-to-operation transitions.

This research seeks to merge aircraft routing and tail assignment problems to address flight cancellations and maintenance-tail conflicts while optimizing cost-effective flight rotations. We propose a mixed-integer linear programming model, utilizing a directed acyclic graph representation, with tasks as nodes and connections as arcs. To boost efficiency, we introduce a clustering method grouping tails with similar characteristics.

Our computational experiments focus on a two-day planning horizon within a European airline network. The results illustrate the model's capability to maintain routing feasibility, minimize rotation changes, and meet specific maintenance criteria. This integrated approach offers a robust solution for navigating the dynamic airline operational landscape, ensuring efficient resource utilization and operational continuity.

Improving Rail Yard Management

Invited Session

Railway Applications

Chair: Marc Meketon, Oliver Wyman, 1 University Square Dr, Princeton, NJ, 08540, United States

1 - An Operational Perspective on AI Driven Switching Software

Kevin Murphy, Cedar AI, Seattle, WA, United States

As organizations increasingly rely on complex networks, the need for efficient traffic management and resource allocation has never been more critical. AI-driven switching software leverages machine learning algorithms to optimize data flow, reduce capacity constraints, build fluidity within the yard, and enhance overall network performance. We will examine key operational benefits, including bowl compliance and the positive impact it makes on yard operations.

2 - Evaluating Railway Network Dynamics with Multi-yard Simulation and Mainline Interaction

Tyler Dick, University of Texas at Austin, Austin, TX, United States, Jiaxi Zhao

When considering the performance, capacity and resiliency of a freight railway network, much attention is given to modeling train delay on mainline links, with a secondary emphasis on modeling the yards and terminals that serve as network nodes. Mainline links are typically modeled separately from yards and terminals, making it difficult to gain a holistic perspective on network performance and the interactions between these disparate facilities. However, interactions between mainlines and yards have been observed to play a critical role in the propagation of congestion across the rail network during historical disruption events, and are thus key to understanding railway network resiliency. To meet this industry need, the objective of this research is to simulate and analyze the dynamic performance and interaction between multiple classification yards and connecting mainlines within a railway network. To accomplish this goal, multiple instances of a classification yard model and a simplified mainline capacity model were integrated into a single AnyLogic simulation. The resulting rail network simulation model is used to investigate and quantify rail network recovery patterns after disruptions to yard operations, providing insights into the factors influencing rail network resiliency and the operational consequences of a yard disruption within a broader network scope. The resulting model and findings can help railway practitioners better understand the impact of operational or infrastructure changes in one terminal on other terminals and connecting mainlines, and make optimal decisions regarding allocating resources, developing train plans, and implementing strategies to mitigate delay after incidents in classification yards.

3 - Modeling Rail Yard and Network Operations

Roger Baugher, TrAnalytics, LLC, Duluth, GA, United States

A computer simulation tool, AnyLogic, has been used to model both yard and network operations. The yard model enables a user to create or import a switching problem and specify a solution which can be compared with an optimal solution generated by Cedar AI's Optiswitch software. The network model is limited to a simple configuration of four yards, yet a variety of operating plans and yard performance parameters can be specified and their impact on trip times evaluated. The intent is to acknowledge the probabilistic nature of railroad operations, a different approach from many models and trip plan systems that treat trip time as deterministic.

4 - Intermodal Terminal Layout Optimization Considering Efficiency and Sustainability

Qianqian Tong, University of Texas at Austin, Austin, TX, United States, Tyler Dick

In 2023, railroads in the United States transported 12.5 million intermodal containers and trailers, accounting for nearly 52% of carloads of total traffic. As railroads move towards decarbonization goals, and traffic from environmentally-conscious shippers shifts from highways to railways, the capacity and investment required to ensure the sustainability and efficiency of intermodal shipments is of prime concern both on the mainline and at terminals. Addressing these issues for road-rail intermodal terminals at a strategic level requires a preliminary understanding of the optimal terminal layout and resource levels to facilitate transshipment of increasing container volumes while promoting performance, reliability, efficiency and environmental friendliness. To better understand the role of expanding intermodal terminals in a low-carbon and energy efficient transportation system, we first propose a mixed-integer programming model and algorithm to solve for optimal facility layout and components for a target throughput volume, and second develop an intermodal transshipment facility simulation model to quantify the systematic impact of various factors on intermodal terminal throughput capacity, performance and emissions. Applying our model, we can maximize intermodal terminal capacity within specified land area constraints while balancing handling efficiencies and carbon emissions. The results can inform strategic investment decisions regarding terminal equipment and facility expansions to promote the sustainability of the overall intermodal supply chain. Meanwhile, this two-stage method also offers insights into identifying and alleviating bottlenecks arising from the intermodal terminal layout and allocated resources at the planning and operations level.

BOM Best Working Paper Competition

Award Session

Behavioral Operations Management

Chair: Ignacio Rios, The University of Texas at Dallas, Richardson, TX, 75080, United States

1 - BOM Best Working Paper Competition - Welcome

Ignacio Rios, The University of Texas at Dallas, Richardson, TX, United States

This is Welcome and introduction to the award.

2 - Enhancing Volunteer Retention: The Role of Experienced Volunteers

Vinit Tipnis, Kelley School of Business, Indiana University Bloomington, Bloomington, IN, United States, Christopher Chen, Fei Gao

Volunteers play a pivotal role in the daily operations of nonprofit organizations (NPOs), yet retaining volunteers remains a critical challenge for NPOs. This study explores a cost-effective approach to improving volunteer retention by leveraging the potential of the existing pool of experienced volunteers. We examine how interactions between experienced and new volunteers impact the latter's retention behavior. Using data of 45,315 volunteers at a food bank over a four-year period, we explore interaction patterns among the volunteers. Our findings indicate that the presence of experienced volunteers in a volunteering shift increases new volunteer retention by 15.5%, with a stronger 71% increase for group volunteers. However, we find that increased familiarity among experienced volunteers negates this positive effect. This negative effect is dependent on the uncertainty inherent in the tasks undertaken by the volunteers. Our study contributes to the volunteer management literature by highlighting the importance of social interactions for volunteer retention and how NPOs can utilize their existing experienced volunteers to enhance new volunteer retention.

3 - Green E-commerce: Environmental Impact of Fast Delivery

Chenshan Hu, Washington University in St. Louis, Saint Louis, MO, United States, Xiaoyang Long, Jiankun Sun, Dennis Zhang

It is well-established that faster delivery in e-commerce increases consumer demand. However, the impact of faster delivery on how consumers place orders (their order frequency and basket sizes) and the subsequent environmental implications are not known. To investigate these questions, we leverage a quasi-experiment involving the opening of a new local warehouse by Alibaba Group, which led to a half-day improvement in the delivery speed for local orders. Through a difference-in-differences analysis, we find that the delivery speed improvement not only increased consumers' monthly purchasing amount by 6.70%, but also increased monthly order frequency by a higher percentage (i.e., 7.74%) and reduced the average order basket size by 0.79%. These results collectively suggest that with faster delivery, consumers purchase more on the platform but do so in more frequent and smaller orders, which implies more packaging and transportation costs for each unit of product sold. Based on these results, we conduct a detailed calibration using both public and company-specific data to estimate the increase in the platform's carbon emissions due to faster delivery. We also explore and identify two mechanisms contributing to the phenomenon: order-splitting and category expansion. We combine these insights with heterogeneous treatment effect analysis to derive managerial implications for the e-commerce platform. In particular, we find that for a platform that implements a threshold shipping policy, raising the free shipping threshold may be more effective than raising the shipping fee to reduce the environmental and operational costs associated with faster delivery.

4 - Delegated Innovation Scouting when Success is Rare: A Behavioral Investigation

Jochen Schlapp, Frankfurt School of Finance & Management gGmbH, Frankfurt Am Main, Germany, Mirko Kremer

Firms involved in the widespread practice of (delegated) innovation scouting face a crucial challenge: How to motivate innovation scouts to engage in extensive search for innovative projects given that search success oftentimes eludes them? Motivated by common scouting practice, we build a principal-agent model to study the optimal structure of formal incentive schemes as well as the performance of contract schemes that rely on discretionary and non-contractible rewards. We then test our key predictions in a controlled laboratory experiment that varies scouts' success chances and their contract type. We find that, irrespective of contract type, performance distortions are strongest in low success probability environments, due to poor incentive design by managers and poor search decisions by scouts. Our results are suggestive of two behavioral biases that reinforce one another when success is rare: (i) superficial fairness, which prevents managers from offer- ing the steep incentives needed to motivate scouts; and (ii) biased probability judgments, which lead both managers and scouts to overweight their success chances. Based on our findings, we derive actionable rec- ommendations on how to improve the design of innovation scouting processes in practice.

5 - Modeling the Influence of Unpaid Effort in Delivery Agents' Choices in Last-Mile Platforms

Lina Wang, The Pennsylvania State University, State College, PA, United States, Stanley Lim, Elliot Rabinovich

We examine decision-making dynamics in the choices that delivery agents make among jobs available in last-mile platforms. Jobs at these platforms comprise the delivery of multiple orders along routes and their compensation typically accounts for the number of deliveries and the length of the routes involved in making these deliveries (from the first to the last delivery). Rarely, do jobs compensate agents for the distance they must travel to make the first delivery in the routes. Traveling this distance (typically referred to as stem distance, deadhead, or empty miles) often constitutes a significant portion of the effort agents put in to complete these jobs. We seek to determine how this unpaid effort influences job selection by agents relative to other job attributes. We obtained job selection data from a last-mile delivery platform and, based on this data, used a structural framework to estimate a dynamic choice model that accounts for the effects of stem distances and other job attributes on agents' job selection decisions. This model also considers the uncertainty agents face regarding the availability and quality of future jobs by accounting for the option value of waiting as well as dynamic selections among agents. We find that an increase in stem distances markedly reduces the likelihood of job selection, overshadowing job attributes such as payout amounts and delivery lead times.

Advancements in Graph Learning and Stochastic Process Optimization

Contributed Session

Chair: Yoonsik Jung, Korea University, Seongbuk-gu, Korea, Republic of

1 - Representation Learning for Event Sequences from a Diverse Range of Stochastic Processes with Attention-based Neural Networks

Francisca Quijada, Arizona State University, Tempe, AZ, United States, Micaela Mercado, Robert Wickham, Kristin Ferguson, George Runger

Event sequences are found in multiple domains where systems generate transactions or encounters over time. Their study is relevant to identify patterns and understand system behavior. Insights about future actions or common patterns benefit from an analysis.

Event sequences can be addressed via feature engineering (FE) and traditional predictive models. FE can include temporal and non-temporal attributes to represent sequences, but FE is a heavy and complex process requiring in-depth domain knowledge and may not fully represent the underlying temporal dependencies between events. We present a methodology for event sequences that vary in length and where events may not occur at periodic intervals. The methodology captures temporal and entity-level static features and compares to traditional FE for several learning tasks. The problem is modeled to aid policy decision-makers and practitioners in the homeless services system and is among the first modern machine-learning applications for event sequence prediction in this domain.

2 - Graphlet Proximity-based Negative Sampling for Graph Contrastive Learning

Myungsoo Choi, Ajou University, Suwon, Korea, Republic of, Hyunjung Shin

Given a set of graphs, labeling each graph is a challenging task: a label indicates whether a protein has a specific function, a chemical molecule is aromatic, and so on. Recent work has aimed to address this challenge by learning unsupervised representations through graph contrastive learning, which places positive pairs close together and negative pairs far apart in the embedding space. However, finding negative graphs that are not false negatives remains a critical difficulty. To tackle this issue, we propose Graphlet Proximity based Negative Sampling, which performs screening on the entire set of graphs using the kernel matrix of graphlets to avoid false negatives. Experiments show that the proposed method can significantly improve the performance of graph contrastive learning by efficiently filtering out false negatives.

3 - Enhancing Graph Contrastive Learning with Edge Distribution and Node Mutual Information

Jeongheun Yeon, Ajou University, Suwon, Korea, Republic of, Hyunjung Shin

Labeling nodes in a graph is time-consuming and expensive. Graph contrastive learning, an emerging method within self-supervised learning, facilitates graph representation learning without relying on label information. Since the labels are sparse or a few, the graph embedding is important for contrastive learning. Given a node of interest, called an anchor, the embedding is determined by selecting the positive samples that are likely to belong to the same class and the negative samples that are unlikely to belong to the same class.

In this study, we propose a novel graph contrastive learning utilizing edge distribution and node mutual information. The former is used to screen out the samples that are likely to be 'true' positive samples or 'true' negative samples. The latter is then used to select the samples that are likely to be near the class-boundaries. Embeddings become more robust with the former and more sophisticated with the latter, which further enhances contrastive learning. Experiments show that the proposed method outperforms the comparison methods by taking advantage of the more robust and sophisticated embedding results.

4 - On a Generalization of the Information Collection Problem

Nastaran Oladzad-Abbasabady, University at Buffalo-SUNY, Amherst, NY, United States, Esther Jose, John Becker, Rajan Batta

We study an Information Collection Problem (ICP) on a graph, where nodes hold valuable information. An agent, with adjustable speed and a given effective range, can collect this information by passing close enough to a node. Nodes are guarded and hence pose a threat to the agent. The objective is to find the path along which the maximum information can be collected, before the first detection occurs. A three-phase approach is presented to tackle this problem. First, we preprocess the graph to identify collectable information along different edges. Second, we develop a Mixed-Integer Non-Linear Programming (MINLP) model to minimize the risk of detection for the agent along each edge. The MINLP assumes that the agent can complete the mission before detection. To enhance the MINLP solution, a heuristic method is introduced in the final step. This method aims to maximize the "expected" information collected by considering agent's detection during the mission.

5 - Overcoming Spatial Feature Limitations in Image Classification through Convolutional Logical Analysis of Data

Yoonsik Jung, Korea University, Seoul, Korea, Republic of, Hong RYOO

In the realm of image classification, Logical Analysis of Data (LAD) utilizes RGB values of pixels as features, leveraging spatial information to classify images. While this approach demonstrates high performance in images with consistent patterns, it suffers from weakened evidence for each pattern when factors for classification are dispersed across various image locations. This drawback is not exclusive to LAD but extends to traditional machine learning methodologies and even neural networks like CNNs.

To address the limitations of spatial features, we aim to classify images based on how well the kernel's shape is embedded within the image data, utilizing convolution operations and optimization models. Toward the end, we propose optimization-based data analytics and LAD pattern generation and report promising results from preliminary experiments.

Simulation Methods and Applications

Contributed Session

Chair: Yuming Zhao, NEU, Shenyang, N/A, China, People's Republic of

1 - A Learning-based Branch-and-price Approach for Solving the Cutting Stock Problem in Steel Industry

Yuming Zhao, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, 110819, Shenyang, China, People's Republic of, Ying Meng, Lixin Tang

In this work we address a cutting stock problem inspired by real-world steel industry plate cutting process in aiming to improve production management and efficiency. A formulation of the model with two-dimensional guillotine cutting is introduced. We propose an algorithm based on branch-and-price method and a deep learning-based approach is applied to improve the algorithm. Experimental results of generated problem instances indicate the algorithm’s efficiency in practical application.

2 - Multi-Manned Mixed-Model Assembly Line Balancing: Integration of Parallel Workstations and Variable Task-Resource Requirements

Wencang Bao, Georgia Institute of Technology, Smyrna, GA, United States, Leon McGinnis, Benoit Montreuil

The assembly line balancing (ALB) problem has been widely investigated for decades. In this paper, we focus on the integration of two popular extensions of ALB that can effectively improve resource utilization rates: parallel workstations (PW), and variable task-resource requirements (VTR). In our context, VTR includes both the choices of resource types and the decision on the resource quantity. In this research, we integrate PW and VTR for mixed-model and multi-manned assembly lines where multiple workers are allowed to work concurrently in one workstation. We formulate the problem by proposing a mixed-integer optimization model to analyze their interactions. Additionally, we develop four separate models, ALB with PW only, ALB with VTR only, ALB with PW first then VTR, and ALB with VTR then PW. We carry out an experiment based on a real-world case study and compare the performance of the integrated model and separate models.

3 - Reduction of Production TIME Variability in the Flexible Work Areas of Mixed-Model Production Systems Using Efficient Particle Swarm Optimization

Hyeongbae Yoon, Ajou University, Suwon-si, Korea, Republic of, Jeonghan Ko

This research investigates a new approach for production system flexibility and related optimization algorithm. In high product variety, the same type of tasks for different product models has large variation in process times. Performing such a task type in the same workstation has limitations in reducing production time variability. To overcome this problem, this research proposes a novel concept of flexible areas in a production line. A flexible area consists of workstations that can perform different tasks depending on product models. To find solutions minimizing production time variability, an efficient particle swarm optimization (PSO) method is developed. In this PSO algorithm, particle properties are affected by product models, and particle states are updated selectively. The results show that the suggested flexible area approach can reduce production time variability effectively. The results also demonstrate the efficiency of the new PSO algorithm, compared to the standard PSO methods. The solution quality and computation times were within reasonable ranges although the number of product models increases. The proposed flexible area approach and efficient particle swarm optimization can contribute to the realization of more flexible production systems and productivity improvement.

4 - Bayesian Optimization with Active Constraint Learning for Accelerating Material Synthesis

GUOYAN LI, Northeastern University, Boston, MA, United States, Yujia Wang, Swastik Kar, Xiaoning Jin

In the realm of manufacturing, the optimization of process parameters is crucial to achieving the objectives of enhanced productivity and quality. The advent of advanced manufacturing technologies introduces complex process dynamics, wherein the relationship between process parameters and quality is often nonlinear and nonstationary. Identifying the optimal process parameters with minimal experimental effort is particularly challenging, especially when manufacturing costs limit the number of feasible experimental trials. Processes such as material synthesis and additive manufacturing are two examples of such complexities. Identifying the optimal process parameters with minimal experimental effort is particularly challenging, especially when manufacturing costs limit the number of feasible experimental trials. Therefore, it's desirable to develop a fast yet accurate method to identify optimal process parameters efficiently using the fewest number of trials.

This study addresses the complex challenge of identifying process parameters for optimal manufacturing outcomes in advanced manufacturing, where nonlinear and costly process-to-quality relationships prevail. We introduce a novel experimental design framework that energizes the optimization of process parameters and feasibility constraint learning with minimal human intervention. Our approach is grounded in two primary methodologies: (1) active multi-criteria sample for constraint estimation and (2) Bayesian optimization-based sample for optimal parameter identification. This integration facilitates the efficient discovery of globally optimal parameter settings and outperforms multiple benchmark models in constraint estimation accuracy. The framework's efficacy is demonstrated through application on a real-world case study involving the synthesis of 2D materials, demonstrating its potential to enhance manufacturing efficiency and quality in complex manufacturing processes significantly.

5 - Revolutionizing Simulation Paradigms with Generative Agent

Young-Jun Son, Purdue University, West Lafayette, IN, United States, Md Tariqul Islam, Seung ho woo, Kamelia Sepanloo, Seonho Woo

The continuous evolution of simulation methodologies has pivotal implications for manufacturing, supply chain management, healthcare, social sciences, and more. Traditional modeling paradigms, including discrete event simulation, system dynamics, agent-based, and physics-based modeling, have long been foundational tools for analyzing complex systems and processes. However, the advent of generative agents rooted in advanced artificial intelligence (AI) poses a transformative potential that could augment or even replace much of these conventional methods. There has been some transformative research in this field, primarily trying to bridge the gap and pave the way towards adopting generative agents for different applications. This presentation explores the developments in generative agents, emphasizing their potential to enhance diversity, adaptability, scale, and scope in simulations. Through a comprehensive review, we will explore the integration of generative agents within industrial applications, using case studies to illustrate their practical benefits and limitations. The discussion will also address the theoretical implications and potential changes in methodology design and implementation for simulation applications. This analysis seeks to provide insights into the future direction of simulation modeling, offering a deeper understanding of how generative agents can redefine the boundaries of traditional modeling approaches.

Managing Organizations to Boost Productivity

Contributed Session

Chair: Changyu Men, KU Leuven, Leuven, Belgium

1 - Local knowledge and operational performance: Evidence from a digitized setting

Changyu Men, KU Leuven, Leuven, Belgium, Marijn Verschelde, Maud Van den Broeke

In digital control rooms, controllers' experience significantly impacts their performance. They accumulate expertise through repetition, termed local knowledge, given the stable and repetitive nature of their tasks. Alternatively, they broaden their skills by working across various workstations, termed neighbor knowledge. Our study investigates the role and impact of these types of knowledge on operational performance, and examines the portability of neighbor knowledge within digital control room settings. For this purpose, leveraging a purposefully built comprehensive dataset from a major European rail system operator, we analyze how workstation-based and train-based experiences influence controllers' operational performance, measured by train delay. Our findings reveal that accumulated work at the same workstation improves operational performance, underscoring the importance of local knowledge. Further, when focusing on operational performance regarding passenger trains, we observe higher performance for controllers with more experience in passenger trains, but also lower performance for controllers with more experience in freight trains, indicating potential drawbacks of neighbor knowledge on operational performance.

2 - Reliable Inference from Human-Centred Datasets with Accumulated Local Effects

Chitu Okoli, SKEMA Business School - Université Côte d'Azur, Paris, France

Despite the increasing promise of big data analysis, operations research and management science (ORMS) problems often involve important human-centred topics with relatively small datasets. This study aims to improve the interpretability and performance of statistical inference techniques used in such cases. We focus on the General Linear Model (GLM) and Generalized Additive Models (GAMs), which are often more reliable than machine learning techniques on smaller datasets. GLM techniques are highly interpretable, and GAMs often provide superior performance as they model nonlinear relationships without prior specification. However, both are prone to issues (collinearity in GLM and concurvity in GAM) that confound the interpretation of correlated predictors.

To address these concerns, we extend accumulated local effects (ALE), a popular technique for visualizing relationships in machine learning models. Our approach combines bootstrapped ALE estimates with new ALE-based effect sizes to produce confidence regions for the predictor variables whose effects can be reliably inferred beyond the sample. ALE provides enhanced interpretability to GLMs and GAMs and is immune to the confounding effects of correlated predictors. Thus, the best-performing model specifications can be readily interpreted without resorting to the artificial exclusion of correlated yet relevant variables. Our results demonstrate that with ALE-based inference, researchers can inductively search for relationships in data without *a priori* hypotheses while effectively ruling out spurious patterns that plague classic hypothesis testing. Whereas such exploratory research is common with machine learning on large datasets, our extensions to ALE bring such benefits to smaller datasets for many important ORMS challenges.

3 - A Generic Approach for Managing Uncertainty in Execution of Large and Complex Projects: Generic Agile Project Management (Gapm)

Homayoun Khamooshi, George Washington University, Washington, DC, United States

Over the past few decades, the concepts of risk and uncertainty rightfully have been the focus of attention for researchers and practitioners of project management alike. It has been even argued that a no risk project is not worth pursuing. While plenty of high-quality research has been generated little practical solutions have emerged. In this paper it is argued that there is no deterministic project management case; but there exists a spectrum of cases stretching from very unlikely deterministic (CPM)projects to very probabilistic scenarios of high-risk projects. The more probabilistic cases to the right of the spectrum require a very dynamic project management approach like Agile. The question to be answered is how we could deal with higher levels of uncertainty which potentially translate into risks in the execution of our projects. Could an agile methodology be prescribed for riskier projects? If yes, how does that approach impacts execution of projects? The paper provides a generic approach for addressing and managing uncertainty in execution of large and complex projects labelled as GAPM: Generic Agile Project Management.

4 - Deep Learning-based White-box Adversarial Attack using Multivariate Time Series Classification Model

Juheon Kwak, Ewha Womans University, Seoul, Korea, Republic of, Dongil Kim

Time Series Classification is widely used in various fields, such as medical, manufacturing, and etc.. Recently, multivariate time series are usually used than univariate time series in classification and various models are used such as Transformer, Recurrent Neural Network(RNN), and etc.. Adversarial attack to time series classification is mainly black-box attack, which is an attack without using the structure and gradient of model. Substitute model is necessary to mimic original model for black-box attack. To make substitute model is so difficult, so black-box attacks are very challenging and uncomplete. However, white-box attack uses all of model structure, so the attack is very easy and fast to success. White-box attacks are usually used to multivariate time series regression. We proposed the adversarial attack method, that is a white-box attack method to multivariate time series classification model using white-box attack. 5 public datasets were used, and the Convolutional Neural Network(CNN), RNN, and Transformer were used as models. Adversarial examples using our method are very similar to original multivariate time series than existing adversarial attack methods. And the trained models are well fooled by our method than existing attack methods.

5 - A Distributionally Robust Approach for Managing Hazmat Emergency Response

Ginger Ke, Memorial University of Newfoundland, St. John's, NL, Canada, Jiahong Zhao, Jie Wu, Longfei Zhang

The potential tremendous threats posed by incidences associated with hazardous materials (hazmat) to the surrounding people and the environment necessitate a well-managed emergency logistics network, especially for random emergencies. Focusing on the distributional ambiguity of the severity level and link disruption, we herein propose a distributionally robust optimization (DRO) model to construct a robust and reliable hazmat emergency response system. Specifically, a joint probability underlying the emergency demand and link disruption is defined to reflect the different characteristics of these two types of randomness. Then, based on the deterministic case, the DRO counterpart is formulated to minimize the total system cost and the worst-case risk over uncertainties. For the optimal solution, the DRO model is reformulated and solved by a Benders decomposition approach. We apply this model and algorithm to a real-world case study and derive managerial insights from numerical experiments to improve practical hazmat emergency management.

Derivative-free Simulation Optimization

Invited Session

Simulation Society

Chair: Sara Shashaani, North Carolina State University, Raleigh, NC, United States

Co-Chair: Hyungkhee Eun, North Carolina State University, Raleigh, United States

1 - How to address derivative calculation in stochastic bilevel optimization

Tommaso Giovannelli, Lehigh University, Bethlehem, PA, United States, Griffin Kent, Luis Nunes Vicente

Bilevel stochastic optimization formulations have become instrumental in a number of machine learning contexts such as continual learning, neural architecture search, adversarial learning, and hyperparameter tuning. Bilevel first-order methods require second-order derivatives that become impractical to compute in optimization or learning problems with a high number of variables or constraints.

In this work, we introduce a bilevel stochastic gradient method for bilevel problems with nonlinear and possibly nonconvex lower-level constraints. We also present a comprehensive convergence theory that addresses both the lower-level unconstrained and constrained cases and covers all inexact calculations of the adjoint gradient (also called hypergradient), such as the inexact solution of the lower-level problem, inexact computation of the adjoint formula (due to the inexact solution of the adjoint equation or use of a truncated Neumann series), and noisy estimates of the gradients, Hessians, and Jacobians involved. To promote the use of bilevel optimization in large-scale learning, we have developed new low-rank practical bilevel stochastic gradient methods (BSG-N-FD and BSG-1) that do not require second-order derivatives and, in the lower-level unconstrained case, dismiss any matrix-vector products.

2 - Efficiency Analysis of Simulation Optimization with Dynamic Stratification of Large Input Spaces

Pranav Jain, North Carolina State University, Raleigh, NC, United States, Sara Shashaani

Stratification is a powerful technique employed to reduce variance, particularly by capitalizing on the local dependence observed in simulation inputs and outputs. In our approach, we integrate stratification into an adaptive sampling procedure within a derivative-free trust-region-based optimization algorithm. This integration allows for the dynamic adjustment of stratification within the optimization framework, responding effectively to the evolving trajectory of the optimization process. Through rigorous analysis and experimentation, we show that our trust-region method, enhanced with stratified adaptive sampling, not only ensures almost sure convergence but also offers significantly improved work complexity when compared to its non-stratified counterpart.

3 - Calibrating Digital Twin via Bayesian Optimization: A root-finding strategy

Yongseok Jeon, North Carolina State University, Raleigh, NC, United States, Sara Shashaani

In this research, we study leveraging root-finding strategies combined with bayesian optimization, which is particularly useful in digital twin calibration tasks. Employing root-finding strategies requires modified acquisition functions and offers unique advantages over traditional minimization strategies. Often, root-finding problem can be reformulated into a minimization problem, and many practitioners have been using these benefits without fully exploring its implications. Such transformations have to be carefully handled, as they may lead to additional challenges, depending on the functional structure or the employed optimization algorithms. Our study suggests that this transformation is not generally recommended, especially when using a continuous surrogate model. We illustrate several motivating examples on this topic, followed by our empirical results through a range of calibration tasks.

4 - Comparative Analysis of Distance Metrics in Distributionally Robust Optimization for Queuing Systems: Wasserstein vs. Kingman

Hyungkhee Eun, North Carolina State University, Raleigh, NC, United States, Sara Shashaani, Russell Barton

This study examines the effectiveness of different metrics in constructing ambiguity sets for Distributionally Robust Optimization (DRO). Two main approaches for building ambiguity sets are the moment- and the discrepancy-based approaches. The latter is more widely adopted because it incorporates a broader range of distributional information beyond moments. Among discrepancy-based metrics, the Wasserstein distance is often preferred for its advantageous properties over ϕ-divergence. In this study, we propose a moment-based Kingman distance, an approximation of mean waiting time in G/G/1 queues, to determine the ambiguity set. We demonstrate that the Kingman distance provides a straightforward and efficient method for identifying worst-case scenarios for simple queue settings. In contrast, the Wasserstein distance requires exhaustive exploration of the entire ambiguity set to pinpoint the worst-case distributions. These findings suggest that the Kingman distance could offer a practical and effective alternative for DRO applications in some cases.

Innovative Approaches to Healthcare Experimentation and Inference

Invited Session

Health Applications Society

Chair: Wanning Chen, University of Washington, Seattle, WA, United States

1 - Estimating and Improving Individualized Treatment Rules with An Instrumental Variable

Bo Zhang, Fred Hutchinson Cancer Center, Seattle, WA, United States

Individualized treatment rules (ITRs) are considered a promising recipe to deliver better policy interventions. One key ingredient in optimal ITR estimation problems is to estimate the average treatment effect conditional on a subject's covariate information, which is often challenging in observational studies due to the universal concern of unmeasured confounding. Instrumental variables (IVs) are widely used tools to infer the treatment effect when there is unmeasured confounding between the treatment and outcome. In this work, we propose a general framework of approaching the optimal ITR estimation problem when a valid IV is allowed to only partially identify the treatment effect. We introduce a novel notion of optimality called "IV-optimality". A treatment rule is said to be IV-optimal if it minimizes the maximum risk with respect to the putative IV and the set of IV identification assumptions. We derive a bound on the risk of an IV-optimal rule that illuminates when an IV-optimal rule has favorable generalization performance. We propose a classification-based statistical learning method that estimates such an IV-optimal rule, design computationally efficient algorithms, and prove theoretical guarantees. We then discuss extension of an IV-based approach to longitudinal settings. We apply our method to study which mothers would benefit from traveling to deliver their premature babies at hospitals with high level neonatal intensive care units.

2 - Randomization-Based Confidence Intervals for the Local Average Treatment Effect

Haoge Chang, Microsoft Research, Cambridge, MA, United States

We consider the problem of generating confidence intervals in randomized experiments with noncompliance. We show that a refinement of a randomization-based procedure proposed by Imbens and Rosenbaum (2005) has desirable properties. Namely, we show that using a studentized Anderson--Rubin-type statistic as a test statistic yields confidence intervals that are finite-sample exact under treatment effect homogeneity, and remain asymptotically valid for the Local Average Treatment Effect when the treatment effect is heterogeneous. We provide a uniform analysis of this procedure.

3 - Dyadic Reinforcement Learning

Shuangning Li, University of Chicago, Chicago, IL, United States

Mobile health aims to enhance health outcomes by delivering interventions to individuals as they go about their daily life. The involvement of care partners and social support networks often proves crucial in helping individuals managing burdensome medical conditions. This presents opportunities in mobile health to design interventions that target the dyadic relationship---the relationship between a target person and their care partner---with the aim of enhancing social support. In this paper, we develop dyadic RL, an online reinforcement learning algorithm designed to personalize intervention delivery based on contextual factors and past responses of a target person and their care partner. Here, multiple sets of interventions impact the dyad across multiple time intervals. The developed dyadic RL is Bayesian and hierarchical. We formally introduce the problem setup, develop dyadic RL and establish a regret bound. We demonstrate dyadic RL's empirical performance through simulation studies on both toy scenarios and on a realistic test bed constructed from data collected in a mobile health study.

4 - Online Learning in Matching Market via Matrix Completion

Zhiyuan Tang, The University of Texas at Dallas, Richardson, TX, United States, Wanning Chen, Kan Xu

Two-sided marketplaces have become increasingly important for facilitating interactions among customers with matching needs across various domains, such as online labor markets, dating apps, and ride-hailing platforms. To achieve specific matching goals, such as optimal or stable matching, platforms need information on pairwise matching outcomes, which can be formalized into a reward matrix. In large-scale markets, missing information in the reward matrix can pose significant challenges for platforms aiming to achieve these matching goals. In this work, we use matrix completion method to learn missing entries from incomplete reward matrix and expedite online learning in two-sided marketplaces. We provide the first minimax optimal Frobenius norm error bound of matrix completion with matching dependence structure and first infinity norm bound of matrix completion with matching dependence structure by a second stage enhancement procedure. By incorporating our method into bandit algorithm, we improve the regret rate in online learning settings.

Award Session

Health Applications Society

Chair: Susan Lu, Purdue University, West Lafayette, IN, United States

1 - Managing Healthcare Information through Algorithms

Mehmet Ayvaci, The University of Texas at Dallas, Richardson, TX, United States

The successful delivery of medical care relies on effectively acquiring and managing information to support decisions. While algorithms can assist in this pursuit, their effectiveness is influenced by input data quality, surrounding processes, and user behavior. These dependencies create challenges in realizing algorithmic value, but also offer opportunities for researchers to improve care delivery. I describe my ongoing research and collaborations focused on using algorithms to address these challenges in healthcare settings.

2 - Improving Patient Access to Biopharmaceuticals

Tugce Martagan, Eindhoven University of Technology, Eindhoven, Netherlands

More than 8,000 biopharmaceuticals are in the global research and development pipeline to treat cancer, diabetes and many other diseases. These drugs are produced using biomanufacturing technologies. With increasing demand and competition, the industry is currently experiencing a growing need for cost-effective and robust production to deliver affordable medicines to patients.
Over the past decade, I have worked with several biopharmaceutical manufacturing companies, hospitals, and government agencies in Europe and the United States. In these projects, we have explored the application of artificial intelligence (AI) and operations research (OR) methods to improve efficiency, safety, and innovation. The real-world implementation of the developed AI/OR models significantly reduced costs and improved productivity with a 50% increase in batch yield and a 40% reduction in carbon footprint. In this presentation, I will reflect on these AI/OR implementations in the industry to advance human health and achieve sustainable development goals.

3 - Transplant health inequities research from an operations perspective

Mustafa Akan, Carnegie Mellon University, Pittsburgh, PA, United States

Health inequity permeates all corners of our health care ecosystem. However, there are many powerful tools to effect real change. In this talk, I review the recent research on deceased donor organ transplant that offers solutions to reduce inequity in access to transplantation and mitigate the impact of those inequities in society at large.

1 - Leveraging AI for SMASH: Social Media Analytics for Adverse Side Effect Hunting

Abraham Seidmann, Boston University, NEWTON, MA, MA, United States, Alon Bartal, Nava Pliskin, Kathleen Jagodnik

Adverse side effects (ASEs) caused by medications cost healthcare systems trillions of dollars annually. To tackle this issue, we have developed an analytical methodology called Social Media Analytics for Side Effect Hunting (SMASH), which employs AI to integrate social media analytics, Named Entity Recognition, and Graph Convolutional Networks. By analyzing social media, ChatGPT responses, and pharmaceutical data, SMASH is capable of uncovering potential ASEs that may not be documented in clinical trials. We have successfully applied SMASH to glucagon-like peptide one receptor agonists (GLP-1 RAs) medications used for treating diabetes and obesity, expected to reach a market value of $133.5 billion by 2030. Our 'Early Warning' SMASH methodology has discovered 21 potential ASEs overlooked during regulatory approval. Potential ASEs are validated by estimating their frequencies (F1-score of 0.79, AUC of 0.82). Our innovative work completely revolutionizes ASE discovery by leveraging cutting-edge AI-driven social media analytics. Our approach goes beyond traditional information systems research, enabling us to proactively mitigate risks for pharmaceutical companies, regulators, and healthcare organizations.

2 - Applications of a new hybrid network-compartmental simulation technique for epidemic modeling

Chaitra Gopalappa, University of Massachusetts, Amherst, Amherst, MA, United States

We developed a new hybrid agent-based network and compartmental (MAC) simulation technique for epidemic modeling. Individuals in a population can either be represented as agents in a network or modeled in a compartmental model that follows a Markov processes structure. An evolving contact network algorithm, developed using deep neural network and optimization, maintains the contact dynamics between the two populations. We applied this simulation technique to multiple applications related to sexually transmitted diseases, including joint modeling interacting diseases that have widely varying disease burden, mechanistic modeling social determinants of health into disease predictions, and cluster detection methods for detection of new outbreaks.

3 - Appointment Scheduling of Outpatient Clinical Services under Uncertain Patient Flows

Yang Yang, Purdue University, West Lafayette, IN, United States, Frank Chen, Qi Feng, J Shanthikumar

We study the problem of appointment scheduling for outpatient clinical services. The patient arrival, appointment cancellation, and appointment attendance are all random, leading to highly variable patient flows in the service system. Analyzing the dynamic decisions is challenging because of the need for tracking the confirmed appointments within the scheduling window. For planning with a long horizon, we show that a probabilistic allocation policy can be efficiently computed by optimizing a closed-form function. The resulting long-term profit approaches the optimal profit asymptotically for scalable systems. For a limited planning horizon, we propose a sequential assignment process implemented with a pre-determined scheduling diagram. We then characterize conditions under which a scheduling diagram policy is optimal. An improvement from a probabilistic allocation policy or a same-day scheduling policy results in a scheduling diagram policy, and the scheduling diagram policy is optimal for two-day schedules. The computation of the proposed scheduling diagrams, through ranking the margins of scalar functions, is simple. An extensive simulation analysis suggests that the system can be efficiently managed through a combination of a two-day policy and an improved probabilistic policy with the former applied to a short scheduling window and the latter to a long scheduling window.

4 - The "Netflix" Model: A New Payment Model For Asymptomatic Disease Management

Huaiyang Zhong, Virginia Tech, Blacksburg, VA, United States, Zhaowei She, Yueran Zhuo, Jagpreet Chhatwal, Turgay Ayer

This paper presents a framework to analyze the effectiveness of Netflix-style contracts in incentivizing payers to increase proactive screenings and pharmaceutical companies to lower treatment prices for asymptomatic diseases such as hepatitis C, breast cancer, colon cancer, and ovarian cancer. These contracts allow payers unlimited access to treatments by making upfront fixed lump sum payments, effectively lowering the unit treatment price as more patients are identified and treated. The authors show that by offering Netflix-style contracts alongside traditional volume-based contracts, pharmaceutical companies can separate payers based on their screening ability, with high-ability payers choosing Netflix-style contracts and low-ability payers remaining in volume-based contracts. This incentive-compatible nonlinear pricing mechanism can encourage payers with high screening ability to increase proactive screenings and lower unit treatment prices for these payers. To support the Biden Administration's initiative to eliminate Hepatitis C, the authors conducted simulations using a micro-simulation model and empirical analyses employing the Almost Ideal Demand System (AIDS) model on Medicaid Drug Utilization data. The findings aim to contribute insights into optimizing screening and treatment strategies for Hepatitis C, aligning with national health objectives.

5 - Saving Lives: Unveiling the Cost-Effectiveness of Liver Cancer Surveillance in Alcohol-Related Cirrhosis Patients

Ali Hajjar, Prince Mohammed Bin Salman College of Business & Entrepreneurship, King Abdullah Economic City, Saudi Arabia, Jovan Julien, Gizem Nemutlu, Hayrullah Mert Sahinkoc, Mary Linton Peters, Fasiha Kanwal, Jagpreet Chhatwal

Alcohol-related cirrhosis is one of the main risk factors for liver cancer. Our objective was to evaluate the cost-effectiveness of biannual liver cancer surveillance in these patients. Employing a microsimulation model, we simulated the progression of liver cancer in individuals with alcohol-related cirrhosis. By integrating data on liver cancer incidence, tumor advancement, real-world adherence to surveillance, and associated economic and health-related quality of life factors, we compared the cost-effectiveness of biannual ultrasound and alpha-fetoprotein surveillance with no surveillance across the patient's lifespan. In alcohol-related cirrhosis patients who continue drinking despite cirrhosis, biannual surveillance remains cost-effective (with an ICER of $19,000/QALY). Similarly, for those who have ceased drinking, biannual surveillance proves cost-effective (with an ICER of $56,000/QALY). These results underscore the cost-effectiveness of biannual liver cancer surveillance in alcohol-related cirrhosis patients, regardless of their drinking status, emphasizing its importance in clinical practice.

Manufacturing and Service Operations Management (MSOM)

Chair: Kedong Chen, Old Dominion University, Norfolk, VA, United States

1 - Firm-Level Small-Worldliness: Exploring the Structural Characteristics and Performance Effects

Yusoon Kim, Oregon State University, Corvallis, OR, United States, Hyunwoo Park

In social or inter-organizational network contexts, small-world structure has attracted much academic attention and is widely thought to enhance creativity or innovative productivity. That is, the so-called small-worldliness has been theorized and studied predominantly at the network levels, while we often observe the effects of such phenomenon at the individual actor levels, such as when we encounter otherwise very distant yet useful individuals or information. In this paper, we consider some individual-level structural properties that induce or increase chances for small-worldliness effects. While the extant literature suggests some network-level structural factors—i.e., cohesive clusters of local ties and nonlocal ties connecting those clusters—as main determinants of small-worldliness effects, at the actor level, we suggest different structural factors that correlate with increased innovative performance. For an empirical test of our thesis, we used network data from the pharmaceutical industry that shows small-worldliness properties and demonstrates much evidence of the effects. Further, we provide some implications of our findings for future research on industrial/supply networks and firm-level innovation.

2 - Industry Concentration and Supply Chain Reconstruction: An Empirical Study

Pankaj Kumar, Virginia Tech, Blacksburg, VA, United States, Xiaojin Liu, Kedong Chen, Feng Cheng

Amidst rising market uncertainties, firms recognize the increasing need to develop efficient, effective, and adaptable supply chains. We conduct an empirical investigation into how a focal firm's position in a concentrated product market affects its supply chain reconstruction, specifically in terms of vertical integration and supply-base differentiation.

Data-Driven and Sustainable Mobility and Logistics System Design

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Sheng Liu, University of Toronto, Toronto, ON, Canada

1 - The Path to Green in Ride-Hailing

Soraya (Nadia) Fatehi, The University of Texas at Dallas, Richardson, TX, United States

Ride-hailing platforms are working toward achieving greener mobility. To this end, they need to implement policies that make driving zero-emission electric vehicles (EVs) an economically attractive choice for crowd drivers. In this study, we propose policies that help ride-hailing platforms meet their carbon-emission sustainability target. Optimal policies suggest that platforms should prioritize allocating demand to available EV crowd drivers, and if necessary, offer subsidies to gas drivers to encourage their participation during this transition to green where the availability of EV drivers is limited. A key finding in our study emphasizes the role of time-to-service guarantee that the platform offers to its riders. If the platform slightly relaxes its tight “on-demand” guarantee, the platform can significantly maximize its earnings while substantially reducing emissions, due to better utilization of EV drivers. Additionally, we compare different incentive structures currently employed by ride-hailing platforms to promote the adoption of EVs and show that, at optimality, they result in the same expected performance. Furthermore, our investigation into the role of EV-rental providers in the platform’s transition to green reveals that if crowd drivers cannot afford the upfront cost of owning an EV and have to rely on EV-rental providers, the strategy of high EV-supply utilization is not always optimal due to higher operating costs. This emphasizes the crucial role of governments in making EV-ownership an affordable option. To assess the practical effectiveness of the policies, we conducted a real-world simulation study in Tampa Bay, USA, using Uber travel times and Tampa Bay’s charging infrastructure.

2 - A Simultaneous Column-and-Row Generation Solution Method for Liner Shipping Network Design

Jun Xia, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Zhou Xu, Roberto Baldacci

The liner shipping network design (LSND) problem aims at creating a set of regular services or rotations of oceangoing ships for a carrier to transport containerized cargo among seaports. Existing literature has shown that finding an optimal solution for the LSND is particularly challenging, even for small-scale problems, because of the complex rotation structure and the joint decision-making on rotation design, fleet deployment, cargo routing, etc. This work presents a new set-partitioning-like formulation for the LSND problem with transshipment costs, featuring an exponential number of variables and constraints. The formulation considers decisions on general rotation configurations of various service components, including but not limited to the ship type, sailing speed, and service frequency. To address transshipment costs correctly, the proposed formulation is associated with exponentially many rotation-dependent variables and constraints, with the result that even solving the linear programming relaxation is a big challenge. To tackle such a challenge, we propose a new simultaneous column-and-row generation (SCRG) solution method and novel speed-up techniques. We embed the SCRG solution method within a branch-and-price algorithm to develop a new exact method for the LSND and test it on two main LSND variants based on different rotation configurations. Results from computational experiments validate the effectiveness and efficiency of the newly proposed solution method. Our work not only enriches the solution methods for the LSND but also enhances the SCRG solution method in general and extends its practical applications.

3 - Machine Learning-Augmented Optimization of Large Bilevel and Two-Stage Stochastic Programs: Application to Cycling Network Design

Bo Lin, University of Toronto, Toronto, ON, Canada, Timothy Chan, Shoshanna Saxe

Motivated by a cycling infrastructure planning application, we present a machine learning approach to solving bilevel programs with a large number of independent followers, which as a special case includes two-stage stochastic programming. We propose an optimization model that explicitly considers a sampled subset of followers and exploits a machine learning model to estimate the objective values of unsampled followers. Unlike existing approaches, we embed machine learning model training into the optimization problem, which allows us to employ follower features that cannot be represented using leader decisions. We prove bounds on the optimality gap of the generated leader decision as measured by the original objective that considers the full follower set. We develop follower sampling algorithms to tighten the bounds and a representation learning approach to learn follower features, which are used as inputs to our machine learning model. Through numerical studies, we show that our approach generates leader decisions of higher quality compared to baselines. Finally, we perform a real-world case study in Toronto, Canada, where we solve a cycling network design problem with over one million followers. Compared to the current practice, our approach improves a transportation metric by 19.2% and can lead to a potential cost saving of $18M.

4 - Staffing Planning for Last-Mile Delivery Drivers

Tamar Cohen-Hillel, UBC Sauder School of Business, Vancouver, BC, Canada, Tolga Cezik, Liron Yedidsion

Staffing planning for last-mile delivery drivers is a crucial process in the logistics industry. It involves determining the optimal number of drivers needed each week to handle the expected volume of deliveries within a specific time frame. In this problem, one must determine the headcount over a planning window, accounting for cross-time constraints, while facing volume uncertainty. We illustrate that this problem is NP-hard and propose a DP-based approximation algorithm. We further show that the approximation algorithm achieves a tight optimality gap. Finally, we show, through computational experiments, that the algorithm performs close to optimality.

5 - Bike Lane Network Expansion: Traffic, Emissions, and Equity Implications

Keji Wei, Tongji University, Shanghai, China, People's Republic of, Sheng Liu, Jingwei Zhang, Xiaoyun Niu

Bike lanes are expanding rapidly in cities worldwide and serve as a major infrastructure policy lever for municipalities to promote cycling and achieve net-zero goals. Meanwhile, the congestion and equity concerns over bike lane network expansion are mounting, and a systematic evaluation of the environmental implications of bike lanes is lacking. Based on real-world data, we develop a mathematical model and empirical framework to estimate the impact of bike lane expansion on urban traffic, carbon emissions, and how different population groups are affected.

Our results indicate significant carbon emission reductions from bike lanes: 50 miles of new bike lanes can decrease emissions by 3.69\% in downtown Chicago. This is a combined effect of demand shift and traffic reassignment. This results in rush hour savings amounting to millions of dollars per year. However, the bike lane expansion is not distributed evenly, with more newly added bike lanes allocated to higher-income communities. As a result, low-income communities face lower coverage, less carbon reductions, and more limited access to bike lane infrastructure than high-income communities. On the other side, lower-income communities still enjoy the significant benefit of improved travel speed due to the network effect, which shows the nuanced equity implications of bike lane network expansion.

2 - How a Recalculation of Workload Alters the Perception of Workload in Nursing

RJ Niewoehner, Kelley School of Business, Indiana University, Bloomington, IN, United States, Harshita Kajaria Montag

Nurses play a pivotal role in patient care, but only if systems can hire enough of them and convince them to stay. Though nurses make up the largest segment of the healthcare workforce, we find ourselves in the middle of a nursing crisis, and a shortage of nurses inevitably leads to overworked nurses. As a proxy for workload, most health systems carefully monitor the “nurse-to-patient ratio." We propose a fundamentally different tactic: using a painstakingly detailed workload tool, we observe how managers react to more accurate definitions of workload, including how they can better allocate and balance work among their staff, all while measuring how the workforce perceives the adjustments in real time. We leverage data from the field and the archive surrounding the introduction of our workload tool. In the field, we surveyed the “perceived workload" of nurses via the NASA-TLX, an industry standard. From the archive, we pulled observations from 71 unique nursing units operated by a large US academic health system. Prior studies generally measure workload using the nurse-to-patient ratio, whereas we consider the individual tasks required for each nurse-to-patient interaction. Moreover, our study monitors how managers react to new workload information and how frontline employees react to changing workload conditions.

3 - First, Do No Harm: Do Staffing Shortages Drive Abuse and Malfeasance in U.S. Nursing Homes?

Jong Myeong Lim, Miami Herbert Business School, Coral Gables, FL, United States, Kenneth Moon, Minjie Park

The U.S. nursing home industry has suffered decades-long understaffing and high worker turnover. Not only does understaffing undermine the quality of nursing home services and care, we empirically examine the novel possibility that it may incentivize unethical practices that cause patients harm. We study the causal linkage between nursing home staffing and chemical restraints, i.e., the improper use of antipsychotic medications to sedate difficult patients. Using nationwide data obtained from the Centers for Medicare & Medicaid Services through Freedom of Information Act requests, we conduct causal analyses that exploit local nursing market wages and changes in local minimum-staffing regulations as exogenous sources of variation in nursing homes' staffing levels. We find that every additional 15 minutes of daily nurse staffing hour per resident reduces a nursing home's usage of antipsychotic drugs by 2.1 residents, on average. Our causal estimates provide supporting evidence for the new CMS nursing home minimum staffing standards finalized in April 2024. Based on our estimates, the new minimum staffing rule will reduce nursing homes' usage of antipsychotic drugs by 36,495 residents, or 16.5%, nationwide. Our findings demonstrate a robust and widespread causal relationship between staffing and the use of potentially improper and harmful practices in healthcare operations.

4 - Capacity Expansion in Emergency Department Network: Impact of Opening Hospital and Hospital-Based Emergency Department on Patient Demand Shift and Operational Performance

Eric Park, Wake Forest University, Winston Salem, NC, United States, Bob Batt, Hyun Seok Lee, Timothy Rainer

We study how patients respond to easier access to emergency care in the form of new EDs opening closer to their location. Our study exploits individual patient’s decision on ED visit choice and tendency and its impact on care outcomes and operational performances due to shift in overall demand and subsequent change in ED congestion levels in two different settings. One ED/hospital opening in a region without any public hospital within 25 km and another ED/hospital opening in a region with already two other EDs within 10 km.

Control of Queueing Systems with Applications to Service and Production Operations

Invited Session

MSOM: Service Operations

Chair: Nasser Barjesteh, University of Toronto, Toronto, ON, Canada

Co-Chair: Amir Alwan, The University of Chicago Booth School of Business, Chicago, IL, United States

1 - A Unified Fluid Model for Large Service Systems with Patience-Dependent or Delay-Dependent Service TIMES

Deniz Simsek, Northwestern University, Evanston, IL, United States, Achal Bassamboo, Ohad Perry, Chenguang Wu

We consider a single-pool many-server queueing system, assuming the service time of each customer depends on the delay of that customer in queue. Such dependence can be due to the customers having finite patience for waiting that depends on their individual service requirement, or due to having their service-time distribution be a function of the time spent in queue. We refer to the former dependence mechanism as “exogenous dependence” and to that latter as “endogenous dependence.” Since exact analysis of the stochastic system under either dependence mechanism is intractable, we propose a deterministic approximation for the (mean) queueing dynamics, referred to as a Unified Fluid Model (UFM). For constant arrival rates, we characterize conditions for the existence of a unique stationary point for the UFM and prove that those conditions always hold when the dependence is exogenous. However, the UFM may possess multiple equilibria, with each equilibrium point being either locally stable or unstable. The implication of the multi-stability of the UFM for the stochastic system is two-fold. First, the stochastic fluctuations in steady state may be an order of magnitude larger than the typical fluctuations in many-server queueing systems. Second, an underloaded or critically loaded system may experience congestion collapse, namely, it becomes severely congested.

2 - Delay Information Sharing in Two-Sided Queues

Mustafa Akan, Carnegie Mellon University, Pittsburgh, PA, United States, Mohammad Delasay, Siddharth Singh

We study the control of two-sided queues via different levels of information on system state. Each side is strategic and consists of patient and impatient agents (who do not tolerate any delay). We derive sufficient conditions under which the match rate is "unimodal" in the specificity of the information.

3 - Invisible Customers in Omnichannel Services

Guanling Yang, Simon Business School, University of Rochester, Rochester, NY, United States, Ricky Roet-Green

In omnichannel services, walk-in customers are physically present in the store and therefore visible to others. However, online customers are typically invisible due to the inherent nature of the online channel. This invisibility poses a significant challenge for customers' decisions about whether to wait for service. In our study, we propose two information systems to address this invisibility and the consequent information asymmetry. In the symmetric information system, customers from both channels only have access to visible queue length information. In the asymmetric information system, online customers have full queue length information, while walk-in customers only observe the visible customers in the queue. We study the strategic behavior of customers and its impact on system performance, comparing these models to the fully-observable queueing model.

4 - Dynamic Control of a Multiclass Omnichannel Production System with Applications to the Restaurant Industry

Amir Alwan, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, Nasser Barjesteh

Omnichannel strategies have revolutionized production systems in various sectors, including the restaurant industry, but have also revealed challenges in demand and operations management. To address these challenges, there is growing interest in dynamic pricing for omnichannel restaurants. Motivated by these considerations, we develop a stochastic processing network model for an omnichannel production system that caters to a market of price- and delay-sensitive customers. The firm offers make-to-order (MTO) and make-to-stock (MTS) goods, available through both walk-in and online channels, at multiple predetermined quote times. The objective is to maximize long-run average profit by making dynamic pricing, production scheduling, and admission control decisions. MTO orders are subject to both earliness and tardiness costs, whereas MTS orders only face tardiness costs, alongside holding costs for the stored MTS goods. Walk-in customers have finite patience and may abandon the system if their wait time is too long. Since this problem appears analytically intractable, we consider an approximating Brownian control problem in the heavy traffic regime. We prove that the optimal policy is a two-sided barrier policy with a state-dependent drift rate. We then propose a joint dynamic pricing, scheduling, and rejection policy by interpreting this solution in the context of the original production system. Finally, we demonstrate the effectiveness of our proposed policy through a comprehensive simulation study and provide managerial insights for the dynamic control of omnichannel production systems.

Spatially Distributed Service Systems

Invited Session

MSOM: Service Operations

Chair: Philipp Afeche, University of Toronto, Rotman School of Management, Toronto, ON, Canada

1 - Demand Equilibria in Spatial Service Systems

Xiaoshan Peng, Indiana University, Bloomington, IN, United States, John Carlsson, Ilya Ryzhov

A service is offered at certain locations (``facilities") in a geographical region. Customers can appear anywhere in the region, and each customer chooses a facility based on travel distance as well as expected waiting time. Customer decisions affect waiting times by increasing the load on a facility, and thus impact other customers' decisions. The service provider can also influence service quality by adjusting service rates at each facility. Using a combination of queueing models and computational geometry, we characterize demand equilibria in such spatial service systems. An equilibrium can be visualized as a partition of the region into service zones that form as a result of customer decisions. Service rates can be set in a way that achieves the best possible social welfare purely through decentralized customer behavior. We provide techniques for computing and visualizing demand equilibria, as well as calculating optimal service rates. Our analytical and numerical results indicate that, in many situations, resource allocation is a far more significant source of inefficiency than decentralized behavior.

2 - Spatial Service Network Design

Sina Hoveida, University of Waterloo, Waterloo, ON, Canada, Hossein Abouee Mehrizi, Ming Hu

This study aims to design a service network in an urban area with continuous demand to maximize social welfare. We assume that customers are sensitive to travel and wait time and seek service at a service location that maximizes their utility. First, we show that the problem of spatial service design and pricing for an urban region with strategic customers is equivalent to a bilevel design problem in which customers can be explicitly assigned to service locations. This helps us to demonstrate that the urban region can be divided into a set of connected and disjoint sub-regions such that, in each subregion, all customers seek service from the same service location. We then derive the relationship between the optimal demand rate served at each service location and the optimal capacity (service rate) of the location. We observe that the optimal service capacity follows the square root rule and show how changes in the wait and travel costs would affect the optimal demand and capacity at each location. Eventually, we characterize the relationship between the optimal service price and arrival rates and show that for locations with higher arrival rates, the optimal service price is lower if service rates are fixed. However, if the service capacity and price are determined simultaneously, the optimal service price is higher at locations with a higher optimal arrival rate.

3 - Pricing Time-Based Contracts

Tonghun Lee, University of California, Berkeley, Berkeley, CA, United States, Ozan Candogan, Yiding Feng

Digital freight brokerages connect shippers and carriers online. However, empty backhaul miles lead to inefficiency because drivers prefer cycles that start and end at the same location but struggle to find return shipments, potentially diminishing drivers' platform participation. To address this, we propose time-based contract design where the platform assigns cycles to drivers, who are compensated for their on-duty time. We use a transportation network model that conceptualizes the interactions between shippers, the platform, and drivers through a game-theoretical framework. We characterize the driver equilibrium with a potential function that reflects the unilateral deviation incentives of all drivers, and market clearing constraint ensuring that overall market conditions are satisfied. Our approach to contract design is grounded on a bi-level optimization problem, where the platform seeks to maximize its profits while adhering to the constraints imposed by the driver equilibrium. With a simple stylized network example, we observe that the platform enjoys a profit improvement after establishing contracts, even when it has access to the same set of cycles as the drivers. For general transportation networks, we explore how the level of sophistication influences the platform's contract decisions. We further address the platform's decision to expand the market on both supply and demand perspectives. Finally, we conduct empirical study with US freight data to validate our model and highlight some important managerial implications of the model.

4 - When A Platform Competes with Third-Party Sellers in Networked Markets: A Revenue Management Perspective

Hongfan Chen, CUHK Business School, Shatin, Hong Kong, Hai Wang

We consider a platform marketplace with both third-party and first-party sellers. The platform charges commissions to third-party sellers and buyers for transactions in the marketplace. Meanwhile, it also directly determines transaction prices for first-party sellers in their sales to buyers. Sellers and buyers are divided into different types with the compatibility captured by a bipartite network. Different types of sellers and buyers are heterogeneous in their cost and utility functions. Given the platform's decisions on prices and commissions, buyers/third-party sellers maximize their own payoffs from demanding/supplying products, and market-clearing conditions are satisfied in the networked market. We develop a convex optimization formulation for the platform's profit-optimal price-commission vector. Moreover, we characterize how the platform's profit-optimal price-commission profile depends on the network structure featured by complement and substitution of agents' trading relation in the marketplace. When introducing additional first-party sellers into the marketplace, we find that the widely-applied greedy strategy can perform arbitrarily bad. The platform needs to take into account the network structure in introducing the additional first-party sellers. For the fairness consideration between the platform and its market participants, we develop an efficient $(1-\epsilon)$-approximation algorithm to obtain a price-commission profile under which a fair allocation of surplus between the platform and its market participants is guaranteed in the equilibrium trades. Lastly, we apply inverse optimization to a real-world dataset to estimate the problem parameters, and provide numerical insight into the platform's revenue management strategy.

5 - Effectiveness of supply-side financial incentives in ride-hailing networks with spatial demand imbalance and strategic drivers

Uta Mohring, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Philipp Afeche, Andre Cire

When matching riders with self-interested drivers over a spatial network, ride-hailing platforms face spatial demand imbalances, which require driver repositioning to serve the total rider demand, and self-interested drivers, who strategically decide whether to participate and if so, when and where to reposition. We study the effects of supply-side financial incentives (wages) on drivers' decisions and the resulting equilibrium and evaluate their effectiveness in achieving the equilibrium under centralized repositioning.

We analyze the steady-state behavior of a ride-hailing network with general topology and general demand imbalance patterns based on a game-theoretic fluid model. We characterize the system equilibrium under decentralized repositioning for various wage policies as well as how the effectiveness of supply-side financial incentives depends on the interplay of the network's spatial configuration, wage flexibility, and the congestion-sensitivity of travel times. More precisely: (i) We identify necessary and sufficient travel time conditions for equilibrium existence. (ii) For networks with constant travel times, we show that the centrally optimal repositioning flows can always be implemented under decentralized repositioning, some wage flexibility is critical to achieve the centrally optimal capacity level and platform profit, and more limited wage flexibility yields inefficiencies in terms of drivers idling. (iii) For networks with congestion-sensitive travel times, the centrally optimal repositioning flows can generally not be implemented under decentralized repositioning, even with full wage flexibility, and decentralized repositioning implies higher capacity and average driver wage rates than centralized repositioning.

Our results provide novel managerial guidelines for the design of supply-side financial incentives under decentralized repositioning.

Information Design in Supply Chains

Invited Session

MSOM: Supply Chain

Chair: Rene Caldentey, The University of Chicago, Chicago

Co-Chair: David Simchi-Levi, Massachusetts Institute of Technology, Cambridge, MA, United States

Co-Chair: Prem Talwai

1 - Information Design and Sharing in Supply Chains

Rene Caldentey, The University of Chicago, Chicago, IL, United States, Clifford Hurvich, Avi Giloni, Yichen Zhang

We study the interplay between inventory replenishment policies and information sharing in the context of a two-tier supply chain with a single supplier and a single retailer serving a Gaussian market demand. We investigate how the retailer's inventory policy impacts the supply chain's cumulative expected long-term average inventory costs in two extreme information sharing cases: (a) full information sharing and (b) no information sharing. We formulate an infinite-dimensional optimization problem whose decision variables are the MA(infinity) coefficients and interpreters them as elements of the Hardy space H2. This representation allows us to use a number of results from H2 theory to compute the optimal cost and characterize a sequence of epsilon-optimal inventory policies under some mild technical conditions. By comparing the optimal solution under full information sharing and no information sharing we derive a number of important practical takeaways. For instance, we show that there is value in information sharing if and only if the retailer's optimal policy under full information sharing is not invertible with respect to the sequence of demand shocks. Furthermore, we derive a fundamental mathematical identity that reveals the value of information sharing by exploiting the canonical Smirnov-Beurling inner-outer factorization of the retailer's orders when viewed as an element of H2. We also show that the relative value of information sharing can grow unboundedly when the cumulative supply chain costs are dominated by the supplier's inventory costs.

2 - Information Sharing in Supply Chains: A Finite Sample Perspective

Prem Talwai, MIT, Cambridge, MA, United States

We study the interplay between inventory replenishment policies and information sharing in the context of a two-tier supply chain with a single supplier and a single retailer serving a Gaussian market demand. We study the setting in which there is no information sharing between the retailer and supplier, where the supplier is further constrained to design an inventory policy using only a finite sample of past orders. We examine the interplay of sampling and approximation in the long-past asymptotics of the cumulative expected inventory cost, and design a sequence of causal, invertible ARMA policies that asymptotically achieve the optimal cost under full information sharing.

3 - Are Relay Networks Always More Expensive Than Point-to-Point Networks?

Himani Ananthula, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Milind Sohoni, Achal Bassamboo

We compare the long-run average costs of operating relay networks—including fixed costs, shipment holdover costs, and staffing costs—versus point-to-point (P2P) networks. Using data from a large trucking company, we find that the driver's likelihood of trip acceptance negatively correlates with the length of the preceding trips. Given this supply uncertainty, our model demonstrates that there exists a threshold on cost parameters above which the relay network is optimal and below which P2P becomes optimal. Additionally, under parameter uncertainty of demand, switching to a more adaptive dynamic staffing policy not only brings cost efficiency but also results in the relay network being the optimal network structure—a win-win outcome for both drivers and service providers.

4 - Planning with Supply Yield Uncertainty: On the Optimality of Linear Policies

Jan Van Mieghem, Northwestern University, Evanston, IL, United States, Riccardo Mogre

I will review work on inventory planning under demand and supply yield uncertainty and present new optimality conditions and explicit solutions for the associated single-period ``newsvendor'' model. In general, the stochastic-optimal order policy is non-linear in the starting inventory level x. The literature has proposed Linear Inflation Rules (LIR) that inflate the classic order-up-to policy. We prove that LIR are only stochastically optimal in the degenerate setting where either demand or (not and) supply yield is uncertain. Given the good performance of LIR we investigate their optimality under two robust formulations and provide bounds. We prove that LIR are robustly optimal when only the support of the demand and supply yield distributions are known. Yet we also provide the optimal distribution-free policy when the first two moments of those distributions are known, which again is non-linear. Both models provide novel, explicit order rules that may be useful for dynamic inventory control. Joint work with Riccardo Mogre (Durham U)

Frontiers in Technology, Innovation, and Entrepreneurship

Invited Session

MSOM:Technology, Innovation, and Entrepreneurship

Chair: Guillaume Roels, INSEAD, Boulevard de Constance, Fontainebleau, 77305, France

1 - The Role of Contextual Information in Customer Reviews: A Field Experiment on a Mental Health Platform

Guang Cheng, National University of Singapore, Singapore, Singapore, Sidika Candogan, Joel Goh, Bilal Gokpinar

Online mental health platforms can increase the accessibility of mental health care by allowing customers to select a therapist from a large pool of vetted professionals. However, customers may find it difficult to choose a therapist best suited to their needs because therapists typically list multiple specializations that tend to overlap significantly. This makes it challenging for online mental health platforms to attract new customers and retain existing ones. Motivated by this challenge, we conduct a randomized field experiment in partnership with Singapore's largest online mental health platform. In this experiment, we empirically investigate whether a simple intervention on the customer reviews--revealing contextual information about the review writers--can improve the platform's ability to attract and retain customers. We find that, relative to the control, treated customers are 42% more likely to book their first therapy session, and they book 87% more sessions in total during the experiment. We also find that customers in the treatment group spend more time searching on the platform, which at least partially explains the improvement in the platform's ability to attract and retain customers. Furthermore, treated customers who have the first therapy session book 36% more sessions with their first therapist chosen, and are twice as likely to write a positive review. Overall, our results suggest that revealing contextual information about the review writers improves the informativeness of customer reviews on mental health platforms, and it is a simple and effective way to increase successful matches and foster long-term relationships between customers and the platform.

2 - Look Before You Leap? An Operational Analysis of Hybrid Entrepreneurship

Zeya Wang, Georgia Institute of Technology, Atlanta, GA, United States, Morvarid Rahmani, Karthik Ramachandran

In this paper, we investigate the ongoing debate between fully committed entrepreneurship and the hybrid approach. Different from committed entrepreneurship, hybrid entrepreneurship involves individuals concurrently pursuing traditional employment and entrepreneurial activities. Through a model-based investigation, we analyze the trade-offs associated with these two approaches and identify the conditions that favor the hybrid approach, as well as situations where a full commitment is optimal. Furthermore, we derive the optimal allocation of effort for entrepreneurs who choose the hybrid approach. Additionally, we examine how various factors, such as the learning environment and cost of launching can impact the entrepreneur's optimal strategy.

3 - Transparent OR Not? Optimal Performance Feedback in Gamified Services

Lin Chen, INSEAD, Fontainebleau, France, Guillaume Roels

In many games or gamified services (e.g., fitness), users often receive feedback upon service completion. Such performance feedback, sometimes presented together with a goal and/or other users' scores, shapes their perception of individual performance (through prospect theory) and relative status (through social comparison). How transparent should service providers be in their disclosure of individual performance feedback to enhance user utility?

In this paper, we employ a Bayesian persuasion framework to determine the optimal information disclosure policy, taking into account whether a goal is specified and whether the other users' scores are communicated. We find that when no goal is specified but the other users' scores are communicated, full (resp., no) information is optimal when users are ahead-seeking (resp., behind-averse). When a goal is specified but the other users' scores are not communicated, the provider should reveal the exact scores to the low-performing users and only tell the high-performing users that they lie in the top range. When a goal is specified and the other scores are communicated, the optimal information policy is again only fully transparent for a subset of users: When users are ahead-seeking, it is optimal to inform users in a range containing the goal that they are in that range; whereas, when they are behind-averse, it is optimal to tell high-performing users their performance is in the top range. Our paper demonstrates how gamified service providers can enhance user utility, and thus increase the value of their service, by engineering the design of their relative performance feedback.

4 - Optimal Loyalty Program Design in a Multichannel Context

Antoine Feylessoufi, Vanderbilt University, Nashville, TN, United States, Ersin Korpeoglu, Mika Sumida

With the advent of booking platforms in the hospitality industry, consumers can now often choose between booking a room directly through the hotel or indirectly through a platform. From a hotel perspective, there is a clear trade-off. Platforms may help hotels reach a larger customer base but it comes at the expense of the profit margin due to commissions. Hotels would like to attract new customers but keep the recurring customers to book directly though their direct channel. We explore theoretically how to design an optimal loyalty program in this unique context and use a novel dataset spanning over 4 years of a group of 12 hotels to calibrate our findings.

5 - Organizational Culture, Innovation and Competitive Performance: A Multi-Level Dynamic Model

Christoph Loch, Cambridge University, Cambridge, United Kingdom, Stylianos Kavadias, Konstantinos Ladas

We develop a dynamic evolutionary model of innovation culture and its organizational effects at three levels. At the front line level, infor- mal bottom-up innovation ideas are driven by emergent interactions governed by cultural norms. As the norms and interactions cannot be monitored, management cannot control culture but only imperfectly nudge it at the second level. At the third level, the culture influences innovation performance and productivity of the firm and is thus rele- vant for the organization’s competitiveness. This approach identifies an explicit plausible pathway of how top-down strategy co-exists with implicit bottom-up driven cultural evolution of innovation.

Summit - 447

Towards Resilient and Equitable Infrastructure and Communities

Invited Session

Public Sector OR

Chair: Andrés González, University of Oklahoma, Norman, OK, 73019, United States

1 - Fairness-based resilience enhancement in network systems

Andrés González, University of Oklahoma, Norman, OK, United States

Modeling and enhancing the resilience of complex systems such as supply chain and infrastructure networks is critical for societal wellbeing. However, when studying resilience using only system-level performance metrics may lead to high inequalities, potentially affecting vulnerable regions and communities disproportionally. Thus, it is critical to develop models that not only consider diverse performance metrics at a system level, but also procure a fair distribution of resources so that risks are reduced among different sectors, and mitigation and recovery actions benefit different actors. To address this, we propose a multiobjective mathematical programming framework that integrates fairness and system-level performance, to unveil key dynamics and tradeoffs.

2 - Dynamic Mode Decomposition Analysis for Resilient Supply Chain Networks

Daniel Cabrera Giraldo, University of Oklahoma, Norman, OK, United States

This study explores the integration of Dynamic Mode Decomposition (DMD) and its Augmented variant (ADMD) with linear programming to model and optimize supply chain operations. We apply DMD and ADMD to derive transformation matrices that capture the temporal evolution of sales. These matrices are then
embedded into a linear programming model to simulate the supply chain dynamics, allowing for the endogenous forecasting of demand rather than relying on fixed
demand inputs. Our findings demonstrate the potential of combining advanced data-driven forecasting techniques with optimization models to enhance decision-making in supply chain operations, providing a more flexible and responsive approach to supply chain management.

3 - Consensus-Based Decentralized Decision-Making for Global Relocation Planning Under Climate Change

Buket Cilali, University of Oklahoma, Norman, OK, United States, Kash Barker, Andres Gonzalez, Ahti Salo

The upcoming climate crisis is a significant driver for the displacement of communities. The adverse and slow-onset climate change impacts are expected to strike people worldwide, causing displacement in great quantities; a problem that has received little attention in operations research. The characteristics of the problem – including the need for long-term planning, uncertainties about the future, and the involvement of diverse populations and multiple locations experiencing different levels of climate change impacts – require a unique approach to handle this problem. For this, we take up approaches that can assist in developing relocation plans to manage climate-change-induced movements with a long-term outlook while using the resources effectively and protecting the well-being and dignity of both displaced and receiving communities. In this study, our primary intention is to strategically plan the relocation of displaced individuals, including determining their destinations and timelines. Our secondary intention is to navigate the complex decision-making processes that arise from the involvement of various local authorities while also considering the broader global humanitarian concerns. We propose a consensus-based approach that compromises the global utilitarian goals and local interests. This approach involves using an altruistic (system-optimal) global model, self-centered (self-optimal) global models, making judgment calls, and iterative usage of a base consensus model by adjusting the decisions until proportional fairness among all participating hosts is achieved.

4 - Sheltering During the Storm: An Analysis of Decision-Making in Flash Flood Events through the Protective Action Decision Model

Paula Penagos, University of Missouri - St. Louis, MO, St. Louis, MO, United States, Trilce Encarnacion

Flash floods represent a significant natural hazard characterized by sudden onset and destructive impact, posing significant challenges to disaster management and public safety. The rapid surge of water resulting from heavy rainfall or other precipitating events can result in high mortality rates due to limited response time and the unpredictability of these occurrences. Effective risk communication and timely action are crucial in mitigating the impacts of flash floods and reducing human and financial losses. However, existing studies do not comprehensively understand individual perceptions and decision-making processes during flash floods, and communication approaches for these natural disasters remain underexplored.

This research aims to bridge these gaps by developing an enhanced communication framework tailored to manage flash flood risks in emerging economies, using the city of Santo Domingo, Dominican Republic, as a case study. This study is grounded in the Protective Action Decision Making (PADM) framework, which integrates environmental and social cues, information sources, and channels to understand individual behavioral responses during disasters. Using a Hybrid Discrete Choice (HDC) modeling within the PADM framework, this research captures behavioral responses through behavioral experiments conducted within the general population of Santo Domingo to determine individual perceptions of flash flood threats, protective actions, and stakeholder trust. The findings contribute to theoretical understanding and practical application in flash flood risk management by developing an enhanced communication framework and providing actionable guidance for stakeholders involved in disaster management efforts, ultimately contributing to the resilience and safety of communities vulnerable to flash floods.

5 - Evaluation of the impact of traditional resilience strategies in supply chains subject to disruptions in times of pandemic

Jose Navarro, University of South Florida, Tampa, FL, United States, Daniel Romero, Gina Galindo

The COVID-19 pandemic has brought unprecedented disruptions to global enterprise networks across many industries. Having resilient supply chains is essential for managing the risk of such disruptions, yet research on development of resilience based strategies during pandemics has been limited. We present a comparative analysis of resilience improvement strategies for supply chains operating during pandemics and provide recommendations for decision makers. Insights from this analysis underscore the interconnectedness of resilience strategies and emphasize the need for their diversification.

1 - Interpretable Policies and the Price of Interpretability in Hypertension Treatment Planning

Wesley Marrero, Dartmouth College, Hanover, NH, United States, Gian-Gabriel Garcia, Lauren Steimle, Jeremy Sussman

Markov Decision Process (MDP) models are commonly used tools for optimizing sequential decisions under uncertainty in medical decision making. If the parameters of an MDP satisfy certain assumptions, the optimal policy is guaranteed to be monotone. Unfortunately, these assumptions are not always satisfied. Our paper defines the price of interpretability, which measures the gap between the optimal and an interpretable policy. We assess the price of interpretability of the best-performing monotone policy and the novel class-ordered monotone policy, which preserves interpretability along user-defined state and action classes. Within the context of hypertension treatment, we demonstrate that the class-ordered monotone policy can be computed faster and achieves greater total quality-adjusted life years across a population of 66.5 million people in the US, compared to the best-performing monotone policy.

2 - Collaboration structures in integrated healthcare delivery systems: An exploratory study of accountable care organizations

Yingchao Lan, University of Nebraska-Lincoln, Lincoln, NE, United States, Aravind Chandrasekaran, Deepa Goradia, Daniel Walker

This study explores the performance implications of collaboration structures in an integrated healthcare delivery system, namely an Accountable Care Organization (ACO). ACOs consist of providers from various stages of the care continuum (pre-acute, acute, and post-acute) that voluntarily assume collective responsibility for the quality and cost of care for a defined patient population. Studies in the healthcare operations management primarily have focused on collaboration within a single organization, shedding little light on this problem. We address this issue by exploring two distinct dimensions of collaboration: partnership scope and scale. Partnership scope measures the presence of providers from the pre-acute, acute, and/or post-acute care-continuum stages, while partnership scale measures the presence of providers within a single care-continuum stage. Leveraging a unique dataset of provider types, collaboration structures, and system-level performance for 528 Medicare Shared Savings Program (MSSP) ACOs from 2013-16, we find that synergies exist between partnership scope and scale with respect to ACO performance. We also show that the benefits of increasing partnership scope are consistent across providers and patient-level analysis. Further, we find that these benefits come at some cost, suggesting an initial cost-quality tradeoff when developing collaboration structures. Our results offer important insights into the healthcare operations management literature on designing effective healthcare delivery systems extending beyond a single organization.

3 - Content Promotion for Online Content Platforms with the Diffusion Effect

Yunduan Lin, University of California, Berkeley, Berkeley, CA, United States, Mengxin Wang, Heng Zhang, Renyu Zhang, Zuo-Jun Shen

Problem definition: Content promotion policies are crucial for online content platforms to improve content consumption and user engagement. However, traditional promotion policies generally neglect the diffusion effect within a crowd of users. In this paper, we study the candidate generation and promotion optimization (CGPO) problem for an online content platform, emphasizing the incorporation of the diffusion effect. Methodology/results: We propose a diffusion model that incorporates platform promotion decisions to characterize the adoption process of online content. Based on this diffusion model, we formulate the CGPO problem as a mixed-integer program with nonconvex and nonlinear constraints, which is proved to be NP-hard. Additionally, we investigate methods for estimating the diffusion model parameters using available online platform data and introduce novel double ordinary least squares (D-OLS) estimators. We prove the submodularity of the objective function for the CGPO problem, which enables us to find an efficient $(1-1/e)$-approximation greedy solution. Furthermore, we demonstrate that the D-OLS estimators are consistent and have smaller asymptotic variances than traditional ordinary least squares estimators. By utilizing real data from a large-scale video-sharing platform, we show that our diffusion model effectively characterizes the adoption process of online content. Compared with the policy implemented on the platform, our proposed promotion policy increases total adoptions by 49.90%. Managerial implications: Our research highlights the essential role of diffusion in online content and provides actionable insights for online content platforms to optimize their content promotion policies by leveraging our diffusion model.

1 - Estimating Treatment Effect from Observational Data Using a Hidden Markov Model

Tongqing Chen, University of Chicago, Chicago, IL, United States, John Birge

Treatment effect plays an essential role in the medical decision-making process and is a critical criterion for drug testing and development. However, with unobservable confounders, the treatment effect estimation can be invalid. In this work, we develop a model using observational data in which the confounder is partially observable to estimate the treatment effect. Moreover, we assume that observability can be correlated with the treatment and confounder which relax the assumptions posted by the existing works. Using maximum likelihood estimators and a hidden Markov Chain structure, the model is proved to be identifiable under some general conditions.

2 - Breaking the Stigma: the Role of AI in Drug Purchases for Sensitive Health Conditions

Tong Shen, University of Connecticut, Storrs, CT, United States, Chen Liang, Jing Peng, Mengcheng Guan, Jianbin Li

The integration of artificial intelligence (AI) has become increasingly prevalent across digital health platforms. Leveraging the introduction of an AI assistant for disease diagnosis and drug recommendations within a major drug category tied to sensitive health issues in an online pharmacy, we investigate how the adoption of AI affects users' purchase behaviors using a difference-in-differences design. We find that the adoption of the AI assistant leads to a significant increase in users' purchases in this drug category by 48.8%, which can be delineated into a 50.7% rise in the purchase of drugs recommended by AI and a 46.3% uptick in the purchase of drugs not recommended by AI. Furthermore, we find that the positive effect of adopting the AI assistant is stronger for users with less experience in related drugs or higher privacy concerns. This finding is noteworthy because it shows that the AI assistant is particularly effective for those who are usually not proactive in seeking healthcare due to limited health literacy or high privacy concerns. Finally, we explore the underlying mechanisms and reveal that the increase in user-initiated drug searches explains about 58% of the increase in the purchase of drugs recommended by AI, and nearly all of the increase in the purchase of other drugs. Our results highlight the potential of AI in improving healthcare access in sensitive medical contexts.

3 - Online Doctor-Patient Endogenous Matching: Theoretical and Empirical Evidence from An Online Consultation Platform

Xiuwei SONG, University of Washington, Seattle, WA, United States, Zhijun Yan, Yong Tan, Lin Jia

Many market outcomes are generated through endogenous matching between parties, such as students deciding which schools to apply to and schools deciding which students to admit; executives choosing which companies to join, and companies deciding which executives to hire, etc. The online healthcare(OHC) market also constitutes an endogenous matching market where patients and doctors mutually select each other based on observable characteristics. We considered the impact of both vertical and horizontal factors on the matching outcomes, where vertical factors indicate the medical capabilities of both doctors and patients, and horizontal factors represent the medical types of both parties. We collected data from a leading OHC platform and employed a two-sided matching model to explore how intrinsic and extrinsic characteristics influence matching outcomes. Our results suggest that the medical capabilities and types of doctors and patients exhibit positive assortative matching. However, while the interaction terms for patient's medical capabilities and types show positive assortative matching, those for doctors display negative assortative matching.

4 - Matrix Bandit with Risk

Kunzhu Xie, Purdue University, West Lafayette, IN, United States, Wanning Chen

Multi-armed bandit (MAB) algorithms are commonly used in clinical trials to dynamically allocate trial drugs to patients based on real-time data. These algorithms aim to identify optimal drugs and dosage (arms) and increase overall medical benefits (rewards), such as inflammation reduction. Traditional MAB algorithms focus on maximizing rewards but often overlook harmful side effects (risks), like pain. Recent literature has explored incorporating safety constraints into the MAB framework to control the frequency of administering drugs and dosages with intolerable risk levels. However, existing methods would suffer from long burn-in periods and high exploration regret when the number of arms is large. This issue frequently arises in two-sided clinical trials, where we need to determine the optimal dosage combination for two drugs. Therefore, we propose a two-phase bandit algorithm, Matrix Bandit with Risk (MBR), leveraging the low-rank structure of both reward and risk matrices. MBR first identifies a subset of potentially optimal arms using low-rank estimations, then applies a doubly optimistic strategy based on UCB to this subset to select one arm at each time step. Simulations show that MBR has lower regret and effectively controls the number of safety violations compared to existing methods.

Enhancing Resilience: Strengthening Healthcare Systems for Preparedness and Response

Invited Session

Health Applications Society

Chair: Su Li, Texas A&M University, College Station, 77840

1 - Makeshift Hospital Utilizations During COVID 19 Pandemic: An Efficiency Problem

Eyyub Kibis, Montclair State University, Montclair, NJ, United States, Musa Caglar, Ali Dag, Anton Ivanov, Ozlem Cosgun, Serhat Simsek

In this study, we develop a compartmental dynamic MIP model to investigate the transmission of the COVID-19 pandemic within a community. We propose policies that will help state governments control the pandemic and reduce patient density at overcrowded hospitals. Our model predictions closely fit the real outbreak data and suggest that the deployment of makeshift hospitals as post-treatment facilities will result in the most efficient use of resources to control the pandemic.

2 - Resilience and Adaptation: Assessing the Effects of COVID-19 on Hospital Efficiency and Quality

Utkarsh Verma, Schulich School of Business, York University , Toronto, ON, Canada, Adam Diamant, Raha Imanirad, Amol Verma, Fahad Razak

This study examines the impact of COVID-19 on various aspects of hospital operations, including clinical efficiency, technical proficiency, and experiential quality. Utilizing a dataset of over 250,000 patient admissions from 15 hospitals in Ontario, Canada, we employ data envelopment analysis (DEA) to assess hospital performance based on variables such as readmission rate, mortality rate, length-of-hospital stay, the number of ED visits and surgeries, and wait time metrics for various inpatient services. We then use bootstrapped DEA scores as dependent variables in a fixed-effect, difference-in-differences regression model with heterogeneous treatment times, to explore the causal relationship between the onset of COVID-19 and a hospital's operational scores. Our findings reveal a statistically significant negative impact on clinical efficiency which can be attributed to the COVID-19 pandemic, whereas technical proficiency and patient experience exhibit resilience amidst well-documented operational challenges. The consistency of these results across various robustness checks and alternative specifications underscores their reliability. Consequently, this study deepens our understanding of the implications that COVID-19 had on hospital operations and provides valuable insights for healthcare management strategies in the face of such disruptions.

3 - Exploring the Relationship Between Health Information Exchange, Experiential Quality, and Medical Malpractice: a Hospital Perspective

Sukrit Pal, Iowa State University, Ames, IA, United States, David Cantor, Anand Nair

This study investigates the relationship between hospital participation in Health Information Exchange (HIE) and medical malpractice lawsuits, and explores the moderating effect of experiential quality on this association. Through a comprehensive analysis of healthcare facilities and court (federal + state) systems, we found that hospitals engaging in HIE tend to experience higher rates of medical malpractice lawsuits. However, our research reveals that hospitals with a strong focus on experiential quality demonstrate a mitigating effect, effectively reducing the adverse impact of HIE on malpractice occurrences. By highlighting the significance of experiential quality in healthcare settings, this study contributes to understanding the intricate dynamics between information exchange initiatives and patient outcomes, offering insights for policymakers and healthcare administrators to enhance quality of care and mitigate legal risks.

4 - Evaluating U.S. Drug Resistance Surveillance Policies: a Dynamic, Multi-Simulation-Optimization Approach

Xuecheng Yin, Oklahoma State University, Tulsa, OK, United States, Dursun Delen, Yue Yuan, Esra Büyüktahtakın Toy

The United States' drug resistance surveillance system provides guidance on which antibiotics are used for the first line treatment of infectious diseases, such as gonorrhea. The system changes the empiric therapy of gonorrhea when the prevalence of resistance to the antibiotic exceeds a certain threshold (e.g., 5%). However, it is unclear how providing first-line treatment guidance based on each region independently instead of changing the first-line therapy for all regions together would impact the system. To address this question, we developed a Dynamic Optimization Multi-Simulation Stochastic Model to project the burden of gonorrhea and optimize the surveillance allocation over multiple regions. We compared several proposed policies for their influence on gonorrhea transmission, cost, and human life quality. Our findings indicate that decreasing the frequency of making decisions will not significantly influence the number of infections. However, decreasing the frequency of making decisions leads to a higher number of infections with resistance to the first-line therapy. Furthermore, switching to a new drug for each region independently leads to a lower number of infections, but increases the cost and decreases individual's life quality in the healthcare system under the current 5% switch threshold. The results will improve if a higher threshold is selected (e.g., 9%), which highlights the importance of optimizing the switch threshold and the increasing frequency of making decisions. Our model is flexible and can be extended to study other diseases with drug resistance surveillance to provide guidance on both interventions and treatment.

5 - Social Network Activation: An Application in Reducing Smartphone Overuse

Shaokang Yang, Virginia Tech, Blacksburg, VA, United States, Idris Adjerid, Jiayi Liu

This paper explores smartphone addiction through the lens of social network analysis. Using data from multiple longitudinal studies that track individual relationships and smartphone interactions, we provide empirical evidence that activating specific parts of one's social network affects smartphone usage patterns. Our results highlights the potential of strategic network interventions in managing digital addiction.

1 - Optimizing Van Loading and Dispatching Operations in Amazon's Last Mile Delivery Stations

Yaniv Mordecai, Amazon, Bellevue, WA, United States, Liron Yedidsion, Rohit Malshe

Amazon Logistics (AMZL) ships packages from hundreds of delivery stations (DS). Every day, each DS loads and dispatches scores of vans to deliver packages to customers. AMZL has been dispatching in batches: vans are grouped by sectors of the station's jurisdiction footprint, and all the vans to each sector are launched in a single wave. This method has several operational advantages, but it also results in driver frustration due to the loss of precious minutes, which could make a difference on the road for safer, less stressed shifts. The transition to a different van launching method is not trivial and requires significant changes to AMZL's modus operandi, and must be backed by sound science. We have tackled this problem from both the business and science perspectives, studied several conceptual and physical design alternatives, and built a robust simulation model to assess the impact each layout can have on both the van launch phase and on upstream logistics inside the DS. We have shown that our suggested design and operational method can conservatively save about 40% of the wave dispatch time, which results in a few additional on-road minutes per route. In this talk, we present the various business, engineering, operations, and science considerations and how they interact with each other. If implemented correctly, the proposed van loading method can revolutionize Amazon's Last Mile operations and yield significant benefits in driver safety, sentiment, and ultimately also performance.

2 - Geospatial optimisation at Amazon

Dipal Gupta

3 - Last mile drivers capacity scaling

Mahdieh Allahviranloo, Amazon, City university of New York, New York, NY, United States, Jin Ye

Capacity planning for last mile drivers is critical for operational efficiency in Amazon last mile planning. Over-solving for capacity can lead to extra headroom in resources. On the other hand, under-solving for capacity results in increased costs due to unmet customer promises and the potential outsourcing of packages. Each additional capacity lever comes with associated challenges and limitations on when and how the additional capacity can be deployed optimally. Carefully chosen capacity levers have the potential to significantly reduce costs and enhance customer service. In this paper, we present a multi-objective optimization model where its objective function takes into account the costs associated with capacity levers, as well as overage and underage costs for delivery service providers. The constraints are set to represent ongoing challenges in adjusting needed capacity for Amazon deliveries. The results of the model, designates the optimum capacity scaling strategy along with the optimum deployment timeline.

4 - Time Series Ensemble Forecasting Models

Abhilasha Katariya, Amazon, Bellevue, WA, United States, Eliot Hijano

We propose a comprehensive framework for improving time series forecasting in logistics by integrating clustering techniques, transfer learning, and ensemble modeling. We introduce a novel clustering method to group similar time series data into clusters, forming a cluster time series model, and employ transfer learning within a hierarchical structure of time series models. Additionally, we extend the ensemble modeling by integrating complementary models like physics-based or off-line models. We demonstrate the effectiveness of our approach in addressing operationally constrained metrics in logistics, offering enhanced forecasting accuracy and enabling informed decision-making.

Measuring the Efficacy of Amazon’s Recommendation Systems

Invited Session

TutORial

Chair: Julie Ivy, University of Michigan, Ann Arbor, MI, United States

1 - Measuring the Efficacy of Amazon's Recommendation Systems

Ozalp Ozer, Amazon, Seattle, WA, United States, A. Serdar Simsek, Xiaoxi Zhao, Ethan Dee, Vivian Yu

Amazon's Fulfillment By Amazon (FBA) program provides assistance to Selling Partners ("sellers," for short) in the form of information sharing, recommendations guiding seller actions (e.g., restock quantity recommendations, excess inventory recommendations), and delegated actions (e.g., automated removals of aged inventory). Amazon's vision is to help sellers make better decisions and achieve better business outcomes.
In this tutorial, we consider the sophisticated optimization models Amazon employs to generate recommendations. For example, if a seller has excess inventory, Amazon recommends actions to increase their sell-through rate, such as creating a sale or Sponsored Product ad. We demonstrate how we measure the efficacy of these recommendation systems on seller-product outcomes (e.g., revenue, units shipped, and customer clicks on product listings, or "glance views"). Measuring such outcomes is a causal inference problem because we only observe each seller-product's "factual" and not their "counterfactual" outcome. We employ causal machine learning methodologies such as double machine learning, causal forest, and doubly-robust forest to separate selection bias from a comparison of "treatment" and "control" sellers. For example, we find that aligning with the restock and excess inventory recommendations, on average, improves several seller-salient outcomes. We also present methods for measuring heterogeneity in the efficacy of these recommendations across seller and product segments, and estimate personalized benefits for each seller-product. Finally, through A/B testing, we find that sharing quantified efficacy information with sellers increases their adoption of Amazon recommendations. Sellers are responding to this messaging, and the duty to them is to rigorously identify causal estimates.

1 - Optimal Update Releasing Strategies Using Multi-Armed Bandits and Review Contents

Mingrui Zhang, University of Denver - Daniels College of Business, Seattle, WA, United States, Yingda Lu

This paper presents a novel approach to optimize game update release strategies by leveraging multi-armed bandits and sentiment analysis of game reviews. We analyzes the content of recent game reviews to determine the optimal type of update to release that maximize the averga positive reveiw rate after the release.

2 - Optimal Ranking Algorithm on Online Health Forum

Zoey Hao, University of Pennsylvania, Philadelphia, PA, United States

As online health forums have been increasingly important to help patients with their concerns on their heath condition in a timely manner, the importance of having effective ranking algorithms that can significantly impact the quality of healthcare information dissemination, user engagement, and even patient outcomes is crucial. Previous work studying ranking algorithms usually consider a series of factors, including relevance, popularity, timeliness, and source credibility. In the context of healthcare forums, the traditional factors remain important but are often insufficient. In this paper, we present an empirical framework for creating a forward-looking ranking algorithm that can boost long-term benefits of platform users.

3 - From Content to Action: Identifying Participatory Engagement in National Statistical Systems

Winry Liu, University of Texas at Austin, Austin, TX, United States

The pursuit of Sustainable Development Goals (SDGs) necessitates robust and inclusive statistical systems. This study develops and validates indicators of participatory engagement in national statistical activities, exploring both theoretical and empirical contributions. Leveraging advanced natural language processing (NLP) techniques, we efficiently identify participatory elements from textual data on official websites. Our research investigates the correlation between these participatory indicators and statistical engagement levels, examining how enhanced participation impacts sustainable development. By integrating additional data, we provide a comprehensive model for assessing participatory practices. The findings offer valuable insights for policymakers and national statistical offices, fostering a deeper understanding of the role of participatory engagement in achieving sustainable development.

4 - Navigating the Realm: The Impact of Virtual reality on Sellers' Revenue and Bidders' Tactics in Online House Auctions

Zhenbin Yan, School of Economics and Management, Tongji University, Shanghai, China, People's Republic of, Zhongyun(Phil) Zhou

Virtual reality (VR) is a promising visual technology that may transform product presentation into a 3D and interactive approach. Even though VR's influences have been widely discussed in e-commerce, most prior literature examines VR's impact on consumer behavior in selling inexpensive and small-size goods such as books and clothing using posting price. Online house auctions in our context significantly differ from prior works in terms of product type, sales mode, and research perspective. Specifically, online consumers show higher quality concerns over valuable products and are more difficult to evaluate products with rich spatial details. Besides, competitive bidding in online auctions allows potential buyers' communication through submitting bids strategically, which is distinct from consumers' independent decision-making in posting price. Given the uniqueness of online house auctions, we follow an economic perspective and conduct empirical analyses with a unique dataset to learn how VR affects sellers' revenue and bidders' tactics. Estimation results show that VR can increase houses' final transaction price and benefit sellers to obtain higher revenue. The positive effect of VR is greater for houses with higher product quality. Additional analyses reveal that VR may make buyers bidding strategically. On one side, VR facilitates buyers to place additional jump bids. On the other side, VR reduces the ratio of late bids in the whole bidding process. Both of them contribute sellers to obtain higher revenue. Our findings add to the literature on VR, the online real estate market, online auctions, and bidding strategies and provide implications for stakeholders in e-commerce.

Chair: Zhiyu Zeng, Washington University in St. Louis, St. Louis, MO, United States

1 - Which Model to Choose for E-Commerce Platforms in Emerging Markets? Centralized Model or Decentralized Model

jingyi peng, University of Science and Technology of China, Hefei, China, People's Republic of, Feng Yang, Zihao Zhang

E-commerce is booming and is increasingly becoming the mainstream shopping method worldwide, giving rise to a variety of e-commerce platforms. However, the performance of operational models varies across different environments. Undoubtedly, Amazon stands as the leader among e-commerce platforms, which we refer to as a centralized platform that requires both buyers and sellers to conduct transactions within the platform. A similar platform is Taobao, the leading e-commerce platform in China. In addition, another operational model has achieved success in recent years—Software as a Service (SaaS), represented by independent website-building platforms such as Shopify and WooCommerce. There are over a dozen of these types of platforms globally and SaaS platforms are frequently featured in many lists of e-commerce platforms. SaaS platforms enable merchants to create their own websites for selling goods, known as the decentralized model.

Throughout the development of e-commerce, countless platform operational models have emerged and faded. Some barely survive without scaling up, while others gradually dominate. We know that adapting to the times is key to success.

Therefore, we hope to delve into discussions on which market environments are most conducive to the development of specific platform operational models: For emerging markets, analyze which operational models best suit their conditions; For competitive markets, examine how platforms with different operational models should strategize to gain more profit and market share.

Furthermore, we can conduct a deeper analysis of the interactions between platforms, merchants, and buyers within different operational models, providing interesting findings and recommendations.

2 - Tweets to Citations: Understanding the Role of Social Media Influencers in AI Research Visibility

Iain Weissburg, UCSB, Santa Barbara, CA, United States, Mehir Arora, Xinyi Wang, Liangming Pan, William Wang

As the number of accepted papers at AI and ML conferences reaches into the thousands, it has become unclear how researchers access and read research publications. In this paper, we investigate the role of social media influencers in enhancing the visibility of machine learning research, particularly the citation counts of papers they share. We have compiled a comprehensive dataset of over 8,000 papers, spanning tweets from December 2018 to October 2023, alongside controls precisely matched by 9 key covariates. Our statistical and causal inference analysis reveals a significant increase in citations for papers endorsed by these influencers, with median citation counts 2-3 times higher than those of the control group. Additionally, the study delves into the geographic, gender, and institutional diversity of highlighted authors. Given these findings, we advocate for a responsible approach to curation, encouraging influencers to uphold the journalistic standard that includes showcasing diverse research topics, authors, and institutions.

3 - Dynamic Content Adjustment For Education Platform: Learning and Maximizing Engagement

Lingfei Zhong, The University of Hong Kong, Hong Kong, Hong Kong

A crucial problem for education platforms is how to strategically design content displayed in the app to maximize the engagement of users. In particular, for those education platforms that offer courses to users, such as Coursera and Duolingo, the design of the content taught to users could significantly affect users' activity and engagement. We focus on the design of sequencing of the levels of difficulties of the different lessons in a course. The difficulty might induce users' passion to conquer new materials, but it might also deter users' confidence, leading to users' quitting. The design of sequencing of the levels of difficulties and its effects could become very complicated even in a deterministic scenario where users' behaviors are well specified. We find that challenging content often deters users instead of encouraging users, and that dynamically adjusting course content too actively might hurt users' engagement. Studying the deterministic case might not be able to provide enough insights for course planners because users' transitions from one learning state to another learning state are highly dependent on users' innate features and users' progression as they study a course. We then propose an algorithm to consider users' innate features, progression in the course, and potential deviation from their learning behaviors, and incorporate the contextual information into the course decision-making process. We hope this algorithm might provide more practical guidance to education platform designers on how to strategically design sequencing of the levels of difficulties for content.

4 - Leveraging Machine Learning to Analyze Social Media Data: Findings from a Pilot Study

Nastaran Khalili, Center for Drug Evaluation and Research, U.S. Food and Drug Administration, Silver Spring, MD, United States, Fatima BarraganHerrera, Blair Coleman, Jill Settle, Sara Eggers, Reza Kazemi-Tabriz, Roberto Delhy

This paper describes an innovative application of machine learning techniques to automate the analysis of cannabis-related discourse extracted from a commercially available social listening platform. Using a de-duplicated, manually analyzed and tagged dataset, we employed the BERT (Bidirectional Encoder Representation from Transformers) model to develop a classification algorithm that replicates the nuanced review and categorization process performed by expert qualitative analysts and generate a relevancy prediction for posts that have not been coded. Through hyperparameter tuning, our approach achieved a recall of 0.88 in predicting relevance. Subsequently, we utilized natural language processing (NLP) techniques to extract themes and topics, as well as medical and health-related conditions around people's experiences mentioned within the social media data and clustered them accordingly. Our study highlights the efficacy of this approach in efficiently analyzing social media data, which can minimize the burden of manual coding of these large, unstructured data and offer insights into publicly posted experiences, behaviors, and perceptions as a complement to traditional qualitative analysis methods.

Managing Industry Advisory Boards

Panel Session

Education Outreach

Co-Chair: Ken Murphy, Merage School - UC Irvine, 4293 Pereira Drive, Irvine, CA, 92697, United States

1 - Moderator Panelist

Ken Murphy, Merage School of Business, UC Irvine, Irvine, CA, United States

2 - Panelist

James Cochran, The University of Alabama, Tuscaloosa, AL, United States

The growth of academic programs in analytics has increased the responsibility and complexity of faculty engagement with industry counterparts. In this panel academic faculty and professionals will share their experience in establishing, managing, and participating in successful industry advisory boards. Issues discussed will include setting board goals, generating industry projects, creating student internships, finding clinical faculty, and managing stakeholder expectations. The question of charging a fee for board membership will also be considered.

3 - Panelist

Jeffrey Camm, Wake Forest University, Winston-Salem, NC, United States

4 - Panelist

Matthew Bailey, Bucknell University, Lewisburg, PA, United States

5 - Panelist

Robin Lougee, KnitWell Group, Yorktown Heights, NY, United States

Human-AI Connection in Digital Platforms

Invited Session

Artificial Intelligence

Chair: Chen LI, City University of Hong Kong, Hong Kong, N/A

Co-Chair: Zhiya Zuo, City University of Hong Kong, Kowloon Tong, N/A

1 - Who Moved My Cheese? Algorithm Reactance in Online Investment Communities

Chen LI, City University of Hong Kong, Hong Kong, China, People's Republic of, Zhiya Zuo, Weiquan Wang, Qiang Ye

Algorithms are being increasingly adopted in online investment communities (OICs) to generate algorithmic predictions of stock performance for OIC content consumers (i.e., investors). Nevertheless, such predictions may pose an identity threat to the OICs' key content producers (mainly consisting of non-professional human analysts), who analyze and forecast stock performance through their content generation in OICs (i.e., analysis articles). We investigate how analyst content generation is adapted in response to the introduction of algorithmic predictions in OICs. Drawing on identity control theory and coping theory, we theorize analysts' coping responses under algorithmic identity threat as an algorithm reactance effect, which manifests in two forms, namely, algorithm differentiation and self-elevation. We further elaborate on the contingent role of algorithm performance and analyst experience in influencing the intensity of the reactance effect. Applying a regression discontinuity in time design, we empirically tested the theorized reactance effect using a unique dataset from Seeking Alpha, an OIC that rolled out algorithmic predictions in May 2019. We found that analysts exhibited convergent differentiation towards accurate algorithmic predictions, while exhibiting divergent differentiation when algorithms performed poorly. Moreover, analysts demonstrated growing productivity and portfolio diversity (i.e., self-elevation), which was found to be negatively moderated by analyst experience. Our study reveals a novel, nuanced algorithm reactance effect in a human–algorithm interaction context and offers managerial implications for next-generation algorithm-empowered OICs.

2 - Investor Engagement In Algorithm-Empowered Online Investment Communities

Zhiya Zuo, City University of Hong Kong, Kowloon Tong, Hong Kong, Chen LI, Weiquan Wang, Qiang Ye

Algorithms are increasingly integrated into online investment communities (OICs) to generate quantitative stock predictions for investors. Albeit a seemingly novel feature, it remains unknown whether and how such predictions reshape investor engagement with peer-generated stock analysis. Drawing upon information foraging theory, we theorize the effects of algorithmic predictions on investors' engagement depth (i.e., the intensity of investors' interactions with analysis articles) and engagement breadth (i.e., the diversity of investors' interactions across various stocks). We collected data from Seeking Alpha, an OIC that introduced algorithmic predictions in May 2019. Using a panel dataset of 43,680 single-ticker analysis articles on 1,820 stocks, we implemented a regression discontinuity in time design to test our hypotheses. Our results reveal a nuanced effect on engagement depth contingent on investor experience and analyst–algorithm prediction incongruity. Meanwhile, algorithmic predictions increase engagement breadth through portfolio diversification. This study contributes to human–algorithm connection in a novel context of online communities by focusing on both depth and breadth of engagement. We further discuss managerial implications for OIC platforms and investors.

3 - The Value and Credibility Judgments of AI-Generated Summaries from Consumer Reviews

Zheyi Xu, University of South Florida, Tampa, FL, United States

Platforms have started to adopt AI-generated summaries from consumer reviews to simplify review consumption and facilitate decision-making. However, we know little about the expected value and credibility of such innovations. To examine this question, we distinguish two formats of AI-generated review summaries: narrative-based and attribute-based. We also evaluate their influence on the expected value and credibility, which are assumed to change in the same direction in prior literature. Drawing on fluency theory and feelings-as-information theory, we propose that narrative-based (vs. attribute-based) summaries generated by AI can improve both perceived helpfulness and perceived credibility. We conducted two complementary laboratory experiments to examine this question and demonstrated several key findings. First, AI-generated narratives were perceived to be more helpful than AI-generated attributes because narratives were perceived to be more fluent. In addition, AI-generated summaries were perceived to be more helpful compared to not providing them, but the provision of AI-generated attributes did not enhance perceived helpfulness. Second, perceived helpfulness and credibility did not improve concurrently because the two formats of AI-generated summaries were similar in credibility. Moreover, providing either format was perceived to be similar in credibility compared to not providing them. Third, we found that when the summaries were provided by humans, the inconsistency between the two outcomes became even greater. Our research provides important theoretical and managerial implications.

4 - Spillover Effects of Generative AI on Human-Generated Content Creation: Evidence from a Crowd-Sourcing Design Platform

Weihong Zhao, University of Maryland College Park, Collage Park, MD, United States, Wen Wang, Siva Viswanathan

This study investigates the spillover effects of generative AI on organic human-generated designs. Using extensive data from an online crowd-sourcing design platform, we examine how the adoption of generative AI influences novelty of designers' organic human-generated creations. Additionally, we examine the moderating roles of designers' AI-expertise and domain-expertise. We employ advanced deep learning models and well-established econometric methods to causally identify the impact. Our findings reveal that initial reliance on generative AI may suppress creativity, but long-term use enhances it. A key set of findings relate to the role of designers' AI-expertise and domain-expertise. We find that AI-expertise as well as domain-expertise, independently and jointly, contribute to the novelty of organic designs. Designers with dual expertise, both AI and domain, benefit the most, highlighting the complementarity of these skills. Moreover, our prompt analysis shows that designers with either AI-expertise or domain-expertise use lengthier, more detailed prompts, leading to improved outcomes. Prompts used by designers with domain-expertise are more distinctive than those used by designers with AI-expertise. Overall, our study carries implications for crowd-sourcing platforms and policymakers, highlighting the economic value of generative AI in the design industry and its role in fostering creativity.

5 - Keep The Positive in The Loop: A Field Experimental Study of The Impact of Integrating Solicited Consumer Feedback in Content Recommendation Systems

Yilin Li, Peking University, Beijing, China, People's Republic of, Changrong Xiao, Chong Wang, Sean Xu, Jiayin Zhang

Recommender systems mostly rely on observed user engagement behavior for training and optimization. Yet, behavioral feedback has known biases in capturing consumers' preferences, which necessitate the inclusion of actively solicited user feedback in recommendation systems. We report findings from a field experimental study of the impact of integrating solicited consumer feedback in content recommendation systems. In collaboration with a significant social media platform, a pop-up survey module was introduced to actively collect content consumers' feedback (satisfied/dissatisfied/uncertain). The solicited consumer feedback was used to adjust video recommendations following either the "boosting" or "filtering" strategy. The results show that the two methods for incorporating solicited consumer feedback have distinctive impacts. The boosting strategy increased content diversity and user activity, especially for new users, while the filter strategy decreased content diversity and user engagement. This research reveals the nuances in the design of the integration of "human" and "algorithm" in "keep-human-in-the-loop" recommender systems.

6 - Keep the Positive in the Loop - a Field Experimental Study of the Impact of Integrating Solicited Consumer Feedback in Content Recommendation Systems

Chong Wang, City University of Hong Kong, Hong Kong, Hong Kong

AI recommenders mostly rely on passively observed user engagement behavior (e.g., clicks, likes, comments) for training and optimization. Yet, passive behavioral feedback has known biases in capturing consumers' preferences, which necessitate the inclusion of actively solicited user feedback in recommendation systems. We report findings from a field experimental study of the impact of integrating solicited consumer feedback in content recommendation systems. In collaboration with a significant social media platform, a pop-up survey module was introduced to actively collect content consumers' feedback (like/dislike the content). The solicited consumer feedback was used to adjust personalized recommendations following either the "boosting" or "filtering" method. The results show that the two methods for incorporating solicited consumer feedback have distinctive impacts. The boosting method increased content diversity and user activity, especially for new users, while the filter strategy decreased content diversity and user engagement. This research reveals the nuances in design the integration of "human" and "algorithm" recommendations in "keep-human-in-the-loop" recommender systems.

Advancing AI: From Classification to Molecular Predictions

Contributed Session

Contributed

Chair: Ayse Dogan, UIUC, 2111 Hazelwood Dr, URBANA, IL, 61801, United States

1 - Comparison of the Physiological Signals to Explain the Personal Anxiety Level

Ayse Dogan, University of Illinois at Urbana-Champaign, URBANA, IL, United States, Richard Sowers, Manuel Hernandez

Anxiety has emerged as a significant health concern in recent times, prompting extensive research into its rapid detection and assessment. Physiological data, often collected through wearable sensors, play a crucial role in this endeavor. However, challenges remain in gathering this data and accurately interpreting the stress levels individuals experience. This study aims to address these challenges by comparing various physiological datasets and their correlation with self-reported stress levels using the STAI6 survey. We analyzed Electrodermal Activity (EDA), Blood Volume Pulse (BVP), Heart Rate Variability (HRV), Temperature (TEMP), and Speech datasets from participants during a TSST, evaluating their effectiveness in explaining self-reported stress levels. Our findings provide insights into the relative utility of these physiological measures in stress assessment.

2 - Training Graph Neural Networks with Consistency Regularization for Molecular Property Prediction

Jongmin Han, Sungkyunkwan University, Suwon, Korea, Republic of, Seokho Kang

Although graph neural networks (GNNs) have proven to be powerful in various molecular property prediction tasks, GNNs often suffer from poor predictive performance when trained with small training datasets. Data augmentation is a viable option to alleviate data insufficiency. However, perturbing molecular graphs may potentially alter their properties, thereby negatively affecting predictive performance. In this study, we propose a consistency regularization method to better utilize data augmentation during the training of a GNN. Various molecular graph augmentations, including atom masking, atom deletion, bond deletion, and substructure removal, are used to obtain multiple augmented views of a molecular graph. By introducing a consistency regularization loss into the supervised learning objective, we encourage the GNN to ensure that the predictions for the augmented views of a molecular graph are close to the prediction for the same graph. Through experimental evaluation, we demonstrate that the proposed method outperforms existing methods that leverage data augmentation, especially when the training dataset is smaller.

3 - Lumped Deep Learning Algorithm Based on Pseudo Inverse Techniques&Mdash;a Prediction Model for Urban Development

Tachia Chin, Zhejiang University of Technology, Hangzhou, China, People's Republic of, Zhibin Zhang, Weihua Chieng

This paper proposes a new machine learning algorithm, called the lumped deep learning algorithm, using the pseudo-inverse and its residue to backpropagate and train the neuron weights. The algorithm relies on the matrix operators, which can be easily implemented with the existing libraries such as EIGEN or LINPACK with high computational efficiency. Needed no gradient information, the loss function and the error function can be defined in many ways without causing much burden on the computational complexity. Since the pseudo inverse is intrinsically a least square method, the loss function may be chosen as the maximum standard deviation error among the training examples. Comparing the average error with the maximum error, we can justify whether the size of a neural network is proper for a specific machining learning task. The pseudo-inverse and its residue is backpropagated with low learning rates to make the annealing process of neural weights causing all examples to gradually agree. When the number of layers and neurons can be determined by the number of independent training examples, the neural network can be easily configured without much trial effort. The city development prediction is used as an example, which involves the prediction of the population growth and the regional GDP growth. Despite the data discrepancy for the pseudo-inverse method, the lumped deep learning can still integrate different categories of data and consolidate them to perform the prediction. The result is compared with the conventional regression analysis, a significant improvement was found and discussed in the paper.

4 - A Comparative Analysis of Number of Alternatives Generated by OpenAI and Cohere Language Models for Technology-Related Decision Making

Minoo Ahmadi, University of Southern California, Los Angeles, CA, United States

This research conducts a comparative analysis of the OpenAI and Cohere language models, specifically evaluating their capacity to generate decision-making alternatives for technology-related queries. Utilizing authentic queries from the Quora platform, two distinct batches of 50 questions each—focused on technology options and comparisons—were analyzed. Questions were manually curated to ensure clear decision-making contexts with a strong technological focus, categorized into "Career Choices" and "Technology Comparisons." Both models were tasked with generating alternatives for each question, guided by a standardized definition of "alternative." The analysis revealed that Cohere consistently generated more alternatives than OpenAI across both batches, suggesting that Cohere's capabilities in practical application and text analysis may enhance alternative generation in decision-making scenarios. This indicates a potential for Cohere to better support human decision-making by providing a broader range of options. These findings highlight the significant role of language models in enhancing decision support systems and suggest that leveraging such technologies can improve the quality of decisions in technology-driven contexts. Future research will further explore the quality and diversity of the alternatives generated and how these models can be integrated into comprehensive decision-support frameworks.

5 - Managing Noise and Lack of Stationarity with AI

Irene Aldridge, Cornell University, New York, NY, United States

Six key problems are known to plague traditional econometric analysis and much of pure machine learning: 1) overfitting, 2) inability to deal with noise in the data, 3) difficulties dealing with missing observations, 4) data non-stationarity, 5) researcher ability and creativity, and 6) researcher personal biases. In this paper we show that Artificial Intelligence (AI), when applied in a knowledgeable and correct way, helps researchers deal with the six problems in a fast and efficient manner, resulting in robust population inferences.

Innovations in Machine Learning for Complex Data Analysis

Contributed Session

Chair: Hyungu Kang, Sungkyunkwan University, Jangan-gu, Suwon-si, Korea, Republic of

1 - Industrial anomaly detection based on foreground-focused diffusion

Hyungu Kang, Sungkyunkwan University, Suwon, Korea, Republic of, Seokho Kang

Recently, diffusion models have emerged as effective tools for unsupervised anomaly detection by leveraging their reconstruction capabilities. To detect anomalies in a query image, noise is incrementally added over multiple time steps, followed by denoising using the diffusion model across the same number of time steps. The reconstruction error serves as the anomaly score. Considerable research efforts have been dedicated to developing effective diffusion models for improved anomaly detection performance. These methods apply the diffusion process to the entire regions of an image. In typical industrial anomaly detection tasks, anomalies can only appear in the foreground region of an image where the target object lies. Thus, applying the diffusion process to the background region is unnecessary. Additionally, the location of the target object can provide important information for the reconstruction. In light of this, we propose a foreground-focused diffusion method that applies the diffusion process exclusively to the foreground region. We separate the foreground and background regions in images using the segment-anything model. During both the training and inference phases, we apply the diffusion process only to the foreground region by masking the background region at each time step. The proposed method can be used as an add-on to any existing diffusion-based anomaly detection method to improve performance. We demonstrate the effectiveness of the proposed method through experiments conducted on manufacturing and medical image datasets.

2 - Comparing various feature selection methods to identify crucial disease-associated biomarkers

Shiva Afshar, Emory University, Atlanta, GA, United States, Eric Dammer, Erik Johnson

Feature selection is critical in machine learning because it enables models to focus on the most important information. While various feature selection techniques exist, many rely on basic methods like filtering, wrapping, embedding, and dimensionality reduction. These methods may be impacted by noise and outliers and lack the ability to perform hyperparameter tuning and feature selection simultaneously. In contrast, advanced techniques involve resampling methods like bootstrapping to evaluate feature stability and relevance across different data subsets. Resampling helps reduce variance in feature selection, making the process less susceptible to outliers or noise in the data. Moreover, joint optimization of feature selection and model parameters can potentially lead to improved model performance and interpretability, particularly in high-dimensional datasets with complex feature interactions. In this study, we compared some current bootstrapping-based methods with basic feature selection methods by assessing their prediction performance in identifying biomarkers related to human disease. This comparison aimed to identify the best method to deepen our understanding of complex biological systems and enhance disease diagnosis and treatment strategies.

3 - Diffusion Domain Adaptation from Source to Target via Schrödinger Bridge

Jinju Park, Ajou University, Suwon, Korea, Republic of, Hyunjung Shin

Labeling newly generated data has been attracted researchers' interests. One widely used approach is domain adaptation, which labels an unlabeled target domain from plentiful labels in the source domain by reducing the distribution discrepancy between the two domains. To narrow the distribution discrepancy, we can leverage one of the most recent generative models, the diffusion model. The diffusion model learns to converse from a data distribution to a Gaussian distribution, and in the reverse process generates data from a Gaussian distribution to a data distribution. Domain adaptation can be achieved naturally by assuming the data distribution in the conversion process as the source domain and the data distribution in the reverse process as the target domain. However, there is a computational burden incurred during the conversion to Gaussian and the reverse process from Gaussian. To avoid the difficulty, we propose a domain adaptation method that employs a Schrödinger bridges for the diffusion model. The proposed method bypasses the Gaussian distribution and directly converts the data distribution in the source domain to the data distribution in the target domain. Experiments show that the proposed method can significantly improve the performance of target domain by effectively adapting the data distribution of source domain.

4 - Towards Improving the Interpretability of Deep Learning

Zhen Lin, Massachusetts Institute of Technology, Cambridge, MA, United States, Dimitris Bertsimas, Rama Ramakrishnan

We develop low depth (up to depth 8) classification trees with hyperplanes to closely approximate neural networks. In this way, we contribute in increasing the interpretability of neural networks. To facilitate the stronger performance of the trees, we develop an optimization-based adaptive learning method to generate additional data for training the trees. We also propose variants of our method based on randomization and the combination of optimization and randomization. This method improves the performance of the trees in approximating the neural networks, and in real-world classification tasks. We show this optimization method performs better than randomization. We report computational results on 59 real-world classification datasets, with different sizes of neural networks with accuracy $\sim 95\%$ relative to the neural network.

1 - Breaking Terrains or Scaling Heights: The Role of AI in Flat versus Hierarchical Startups

Xiaoning Wang, University of Texas at Dallas, Richardson, TX, United States

We examine whether artificial intelligence (AI) facilitates the success of flat startups or hierarchical startups. We explore the interaction effect between AI adoption and startup hierarchy by combining startup data from Crunchbase, patent application data from USPTO, and detailed employee job descriptions from LinkedIn. We find that while the adoption of AI helps flat companies achieve better commercial success, the adoption of AI also helps hierarchical companies achieve better innovation performance. The mechanism tests indicate that, on the one hand, AI can improve the organization's coordination capabilities by automating specific sections in the operation and production process, thereby streamlining the company's operational management, avoiding the disorder of flat organizations, and better achieving economies of scale. On the other hand, using AI can also enable companies to expand the scope of information acquisition and integration, thereby breaking the barriers of information sharing within hierarchical companies and improving innovation performance. These results not only provide new evidence for the interaction between AI and organizational structures but also demonstrate that AI, as a general-purpose technology, has multiple application formats and corresponds to a variety of management models depending on the types of technology used and the characteristics of the establishment within each firm.

2 - Exploring the Dynamics of Hashtag Use and Comment Toxicity on Social Media

Anna Gao, University of Pennsylvania, Philadelphia, PA, United States

The advent of social media has revolutionized how information is disseminated and discussed globally. This project explores the role of informational cues, such as hashtags used by content creators, in fostering safe online communities, with a particular focus on comment toxicity in social media discussions. Using Twitter's API, we collected tweets and engagement metrics from a week-long sample, and used the Trump Trial as an initial case study. We aim to understand what drives toxic comments during ongoing, high-profile events. In particular, we apply zero-shot learning to classify tweets into categories of support, opposition, or neutrality towards Trump and discover that tweets opposing Trump receive higher engagement and more negative sentiment. Additionally, we assess hashtag relevancy using a pre-trained language model and find that higher relevancy scores correlate with increased tweet impressions, while greater variance in relevancy scores reduces engagement. Our preliminary analysis reveals key insights into hashtag relevancy and comment toxicity. We found a positive correlation between average relevancy and average comment toxicity, indicating that less relevant hashtags to the tweet's content are less likely to attract toxic comments. These findings suggest that the strategic use of relevant hashtags can mitigate toxic interactions and foster healthier online discussions. By understanding and leveraging these dynamics, content creators can make smarter decisions to create a safer digital world.

3 - Data and Algorithm: Designing Marketplace Analytics for Platform Sellers

Yi Liu, University of Wisconsin-Madison, Madison, WI, United States, Fei Long

The rapid growth of e-commerce giants and the abundance of data has spurred the development of AI-powered analytics services, such as competitive intelligence and automated pricing, which enables marketplace sellers to make informed, data-driven decisions. Third-party providers (e.g., Jungle Scout and Helium 10) compete with platforms themselves (such as Amazon's brand analytics) in offering marketplace analytics. Yet we are witnessing platforms adopt various strategies in sharing data with third-party analytics providers, ranging from restrictive to permissive (e.g., permitting data scraping) with some even actively facilitating (e.g., API sharing). In this paper, we ask *why* and *how* an e-commerce platform may benefit from sharing data with third-party providers, despite the platform's inherent advantages in data access, and the capability to design its own analytics services for better control over sellers' actions. We also study how platforms should design their analytics services, modeled as an algorithm to predict market competition levels. We find that the platform maximizes its own sales commissions by providing an over-optimistic analytics service. When market competition is moderate, this may lead to sellers' reluctance to use the platform's analytics service, resulting in a lose-lose situation, and prompting the platform to share data with third-party providers. However, in highly competitive markets, over-optimistic predictions can actually benefit sellers. In this case, the platform adopts a more restrictive data-sharing approach. Furthermore, when the platform can control the accuracy of third-party analytics via API access, it shares data in a larger parameter space, and it shares broader data when market competition intensifies.

4 - Memory and Beliefs in Financial Markets: A Machine Learning Approach

Zhongtian Chen, University of Pennsylvania, Philadelphia, PA, United States, Jiyuan Huang

This paper shows that memory shapes investor beliefs and influences trading activities in financial markets. Using earnings forecasts by financial analysts as proxies for investor beliefs, we extract their memory and recalls by training a machine learning memory model. The extracted recalls strongly predict stock returns. Additionally, dispersion in recalled episodes predicts investor disagreement and trading volume, indicating that memory can be a powerful microfoundation for disagreement. We further document new facts about memory that are directly elicited from market data. Compared to an optimal benchmark trained to fit realized earnings, investor memory is distorted in two key ways. First, investors over-recall distant episodes in regular times but under-recall them during crisis times. Second, investor memory overweights the importance of past earnings forecasts, while the optimal benchmark mainly considers other firm fundamentals beyond earnings. These distortions in memory predict both forecast errors and key behavioral biases, including the presence of overreaction and underreaction.

ENRE: Electricity

Chair: Daniel Bienstock, Columbia University, New York, NY, United States

1 - Scalable Multi-Period Ac Optimal Power Flow Utilizing Gpus

Mihai Anitescu, Argonne National Laboratory, Lemont, IL, United States, Sungho Shin, Vishwas Rao, Michel Schanen, D. Adrian Maldonado

There has been a growing interest in solving multi-period AC OPF problems, as the increasingly fluctuating electricity market requires operation planning over multiple periods. These problems, formerly deemed intractable, are now becoming technologically feasible to solve thanks to the advent of high-memory GPU hardware and accelerated NLP tools. This study evaluates the capability of the ExaModels.jl and MadNLP.jl tools for GPU-centered nonlinear programming to tackle previously unsolvable multi-period AC OPF instances. Our numerical experiments, run on an NVIDIA GH200, demonstrate that we can solve a multi-period OPF instance with more than 10 million variables up to 10−4 precision in less than 10 minutes.

2 - Tbd

Matias Villagra, Columbia University, New York City, NY, United States

3 - Alternating Methods for Decomposing Large-Scale AC OPF with Unit Commitment Decisions

Matthew Brun, Operations Research Center, MIT, Cambridge, MA, United States, Thomas Lee, Dirk Lauinger, Xin Chen, Andy Sun

In this work, we present an alternating penalty method tailored for solving large-scale, multi-period AC OPF problems with discrete unit commitment (UC) decisions. This method alternates between solving AC and UC problems, allowing for decomposition into a set of continuous, single period AC OPF problems and mixed-integer linear device level UC problems. We introduce a variety of additional techniques, including SOC relaxations, power ramping approximations, and line switching heuristics, that improve solution quality. We evaluate the effectiveness of this algorithm on test cases from the Grid Optimization Competition, Challenge 3, demonstrating competitive performance relative to other algorithm, and compare our solutions to a global lower bound.

Data Mining

Chair: Wenbo Sun, University of Michigan Transportation Research Institute, Ann Arbor, MI, United States

Co-Chair: Yinan Wang, Rensselaer Polytechnic Institute, Troy, United States

1 - Fast Convergence of Retraction-Free Distributed Riemannian Gradient Descent

Youbang Sun, Northeastern University, Boston, MA, United States

We investigate non-convex optimization algorithms with orthogonal constraints. Conventional algorithms for this setting require either manifold retractions or other types of projection to ensure feasibility, both of which involve costly linear algebra operations (e.g., SVD or matrix inversion). On the other hand, infeasible methods are able to provide on par performance with higher computational efficiency. We propose a Decentralized Retraction-Free Gradient Tracking (DRFGT) algorithm, for which we establish both global and local convergence results over networks. Numerical experiments demonstrate that DRFGT performs on par with the state-of-the-art retraction based methods with substantially reduced computational overhead.

2 - Robust Continual Graph Completion for Adrd Knowledge Discovery

Shuteng Niu, Bowling Green State University, Bowling Green, OH, United States

Alzheimer's disease and related dementias (ADRD) are s group of neurodegenerative disorders that affect cognition, behavior, functional ability, and memory, with significant economic, medical, and social impacts. Despite extensive research, effective treatments and our understanding of ADRD remain insufficient. Recent advancements in non-pharmaceutical and pharmaceutical interventions, supported by modern computational methods, have shown promising results. Among state-of-the-art approaches, Knowledge Graph Completion (KGC) on graph-structured data demonstrates high potential in handling the complexity and multifunctionality natures of ADRD. Researchers have used the MEDLINE database to develop KG datasets and applied various KGC models, including traditional translational methods and advanced Graph Neural Networks (GNNs). However, current methods face two critical challenges, poor adaptation to growing KGs and vulnerability to adversarial attacks. Retraining larger KGC models is often prohibitively expensive, and graph-structured data is highly sensitive to adversarial attacks, leading to significant performance degradation in ADRD-related tasks, including but not limited to drug development, treatment planning, and risk prediction. Our research addresses these issues by developing a graph-based continual knowledge discovery framework for ADRD with robustness to adversarial attacks. With dynamic adaptation to growing KGs and resistance to adversarial attacks, our framework aims to improve the reliability and effectiveness of ADRD-related applications. This approach promises significant advancements in the field, providing more accurate and resilient tools to tackle this critical public health issue.

3 - Human Body Modeling for Vehicle Optimization via Inducing Points

Chang Li, University of Michigan, Ann Arbor, MI, United States, Wenbo Sun

Computer simulation models provide efficient and cost-effective alternatives for conducting physical experiments. For example, virtual crash testing simulations using morphed human body models (MHBMs) are well-adopted as anthropomorphic test devices are limited. However, due to computational constraints, it is infeasible to perform virtual crash testing across the entire population. This limitation demonstrates the need to select a subset of representative occupants for efficiently predicting population-wise injury risks. In this study, we introduce a novel method for selecting inducing points, which aids in determining the optimal size and placement of representative occupants. We employ the K-means clustering algorithm to identify inducing points that explain the variability within each gender's population. Additionally, we have developed Gaussian process (GP) models, based on these inducing points, for predicting population injury risks. We conducted a case study using MHBMs to analyze various injury outcomes under differing crash conditions. The results demonstrated that the selected representative occupants, optimized for size, accurately represent the entire population. Furthermore, these findings highlight the potential for efficiently achieving safety equity based on the model's predictions.

Ethics in Action: Operationalizing Fairness in Algorithmic Decision-Making

Invited Session

Data Mining

Chair: Hadis Anahideh, University of Illinois Chicago, Chicago, IL, United States

1 - Finding Representative Group Fairness Metrics Using Correlation Estimations

Samuele Scaglioni, University of Illinois Chicago, Canoga Park, CA, United States, Hadis Anahideh, Nazanin Nezami

It is of critical importance to be aware of the historical discrimination embedded in the data and to consider a fairness measure to reduce bias throughout the predictive modeling pipeline. Given various notions of fairness defined in the literature, investigating the correlation and interaction among metrics is vital for addressing unfairness. Practitioners and data scientists should be able to comprehend each metric and examine their impact on one another given the context, use case, and regulations. Exploring the combinatorial space of different metrics for such examination is burdensome. To alleviate the burden of selecting fairness notions for consideration, we propose a framework that estimates the correlation among fairness notions. Our framework consequently identifies a set of diverse and semantically distinct metrics as representative of a given context. We propose a Monte Carlo sampling technique for computing the correlations between fairness metrics by indirect and efficient perturbation in the model space. Using the estimated correlations, we then find a subset of representative metrics. The paper proposes a generic method that can generalize to any arbitrary set of fairness metrics. We showcase the validity of the proposal using comprehensive experiments on real-world benchmark datasets.

2 - Individual-Level Explanation in the Context of Model Multiplicity

Parian Haghighat, University of Illinois at Chicago, Chicago, IL, United States, Hadis Anahideh

The phenomenon of Model Multiplicity (MM), also known as predictive multiplicity or the Rashomon effect, arises when multiple machine learning models perform equally well on a prediction task. Studies indicate that such models may exhibit significant internal differences, leading to inconsistent predictions for individuals. This poses challenges in providing counterfactual explanations (CEs), which are crucial for offering recourse recommendations. To address this issue, we propose a model-agnostic, individual-level solution involving the construction of uncertainty sets for optimal models. Our framework aims to select the best model for each individual while considering factors such as robustness of CEs and fairness, crucial for decision-making in high-stakes domains. These uncertainty sets are designed to encompass the most plausible explanations of the optimal model with high confidence. Theoretical and experimental analyses demonstrate that our framework satisfies properties lacking in existing methods, with minimal trade-offs in accuracy. We illustrate the effectiveness of our approach using real-world datasets, showcasing how our framework can enhance trust in model explanations.

3 - What Makes Systemic Discrimination, "Systemic?" Exposing the Amplifiers of Inequity

David McMillon, Emory University, Atlanta, GA, United States

Drawing on work spanning economics, public health, education, sociology, and law, I formalize theoretically what makes systemic discrimination “systemic.” Injustices do not occur in isolation, but within a complex system of interdependent factors; and their effects may amplify as a consequence. I develop a taxonomy of these amplification mechanisms, connecting them to well-understood concepts in economics that are precise, testable and policy-oriented. This framework reveals that these amplification mechanisms can either be directly disrupted, or exploited to amplify the effects of equity-focused interventions instead. In other words, it shows how to use the mechanics of systemic discrimination against itself. Real-world examples discussed include, but are not limited to, reparations for slavery and Jim Crow, vouchers or place-based neighborhood interventions, police shootings, affirmative action, and Covid-19.

4 - Finding Representative Group Fairness Metrics Using Correlation Estimations

Hadis Anahideh, University of Illinois Chicago, Chicago, IL, United States

It is of critical importance to be aware of the historical discrimination embedded in the data and to consider a fairness measure to reduce bias throughout the predictive modeling pipeline. Given various notions of fairness defined in the literature, investigating the correlation and interaction among metrics is vital for addressing unfairness. Practitioners and data scientists should be able to comprehend each metric and examine their impact on one another given the context, use case, and regulations. Exploring the combinatorial space of different metrics for such examination is burdensome. To alleviate the burden of selecting fairness notions for consideration, we propose a framework that estimates the correlation among fairness notions. Our framework consequently identifies a set of diverse and semantically distinct metrics as representative of a given context. We propose a Monte Carlo sampling technique for computing the correlations between fairness metrics by indirect and efficient perturbation in the model space. Using the estimated correlations, we then find a subset of representative metrics. The paper proposes a generic method that can generalize to any arbitrary set of fairness metrics. We showcase the validity of the proposal using comprehensive experiments on real-world benchmark datasets.

5 - From Treatment to Outcome: Advanced Causal Inference for Resource Evaluation through Mediator Analysis and Counterfactual Estimation

Hadis Anahideh, University of Illinois Chicago, Chicago, IL, United States

This paper introduces a novel framework that integrates causal inference and machine learning to enhance the analysis of treatment effects and resource allocation. The proposed approach employs a multistage methodology to bridge the gap between predictive modeling and causal analysis, addressing the challenges posed by the absence of counterfactuals in historical data. The framework consists of two primary stages: the first involves using machine learning models to establish pre-treatment baselines and identify at-risk observations, while the second applies causal inference techniques to evaluate the impact of interventions and assess post-treatment outcomes with machine learning. This integrated approach allows for a nuanced understanding of interventions' immediate and long-term effects, providing policymakers with actionable insights for more effective decision-making. The paper illustrates the efficacy of this framework through detailed case studies, including synthetic data and an educational setting focused on financial aid interventions. The results demonstrate the framework's potential to improve intervention strategies and resource allocation by offering dynamic, time-sensitive evaluations. The paper concludes with a discussion of the significance of the framework and recommendations for future research.

Advanced Data Analytics for Energy Transition

Invited Session

Data Mining

Chair: Kailai Wang, University of Houston, Houston, United States

1 - Uncovering the Drivers of Alternative Fuel Vehicle Adoption in California: A Study of Latent Attitudes, Socio-Demographics, and Neighborhood Influences

Kailai Wang, University of Houston, Houston, TX, United States

Promoting the use of alternative fuel vehicles (AFVs) has become a long-term transportation strategy in California, which can bring a broad range of social, economic, and environmental benefits. Based on a sample of 3260 California residents from the 2018 California Panel Survey, this study explores the impacts of latent attitudes, socio-demographic characteristics, and neighborhood effects on consumers' current vehicle fuel type choice and their interest in purchasing or leasing an AFV in the future. One joint integrated choice and latent variable (ICLV) model is estimated to understand the taste heterogeneity within different population segments. The results suggest that latent attitudes towards environment, new technologies, car-utilitarianism, and residential location preference play critical roles in individuals' adopting new vehicle technologies. A range of socio-demographics, including age, race, gender, student status, education level, income level, household size, housing tenure, housing type and residential parking also make effects. Exposure to BEVs in both residential location and worksite has positive influence on AFV adoption, although public EV charging stations were not found to be essential factors since our respondents may mainly rely on home chargers. Moreover, the study suggests that individual's current user experience with AFVs has positive effect on their future interest in AFV. Overall, we predict the maximum market penetration of AFVs could be 41% of adult population. The findings offer detailed guidance on crafting California's transport policy to promote AFV, regarding the heterogeneity of the population's preferences and attitudes.

2 - Energy Equity-Aware Planning of Community Microgrid

Behnam Sabzi, University of Houston, Houston, TX, United States, Gino Lim, Jian Shi

As global energy systems face increasing challenges from climate change, social disparities, and infrastructure vulnerabilities, community microgrids have emerged as a critical solution for promoting sustainable and equitable energy access. This paper addresses the significant gap in energy equity within low-income neighborhoods through the strategic implementation of community microgrids, proposing three new community-based equity metrics. We introduce a two-stage stochastic mixed-integer programming model that effectively integrates the Community Equity Index (CEI) into the microgrid planning process. The first stage focuses on investment decision-making, while the operational planning subproblem is addressed in the subsequent stage utilizing Benders decomposition.

Our framework accounts not only for financial sustainability but also enhances the resiliency and environmental metrics of the target communities. The simulation results are promising, showing that our approach significantly outperforms traditional grid dependency by improving financial returns, reducing environmental impacts, and enhancing the resiliency of energy systems against uncertainties. Specifically, the proposed microgrid framework demonstrates a marked improvement in the Community Equity Index, ensuring that the benefits of energy advancements effectively reach underserved populations.

This study contributes to the literature by defining three new community-based equity metrics, providing a scalable and efficient solution technique for energy planning, and highlighting the role of equity considerations in community microgrid implementations. The findings are particularly relevant for policymakers and practitioners focused on integrating equity into energy planning and operations.

3 - Equitable Power Grid Restoration Considering Decision Maker's Risk Tolerance

Gino Lim, University of Houston, Houston, TX, United States, Behnam Sabzi, Jian Shi, saeedeh abbasi, Masoud Barati

This study addresses the urgent need for robust power system restoration strategies in the face of increasing environmental hazards such as hurricanes, floods, and tornadoes. As climate-related disruptions pose significant threats to power grid reliability, there is a critical demand for strategies that ensure equitable and efficient power restoration. This paper introduces a novel robust optimization (RO) model that integrates an equity-aware approach within a graph partitioning problem (GPP) framework, accommodating the varying risk tolerances of decision-makers concerning uncertain transmission line statuses.

4 - Power Demand Classification Using Pso-Based Ensemble Method

R. J. Kuo, National Taiwan University of Science and Technology, Taipei, Taiwan, Zhen-Xuan Xu

Time series data, where each data point is associated with time, finds applications in diverse fields such as engineering, management, and healthcare. The current study aims to propose a method to enhance the performance of time series classification. The proposed method utilizes MiniRocket to extract features from time series initially and then employs a particle swarm optimization (PSO) algorithm for an ensemble learning method with random forest (RF), XGBoost, and LightGBM for classification due to their explainability. The proposed method is evaluated using Italy's power demand data, comparing it with multi-layer perceptron (MLP), support vector machine, RF, XGBoost, and LightGBM in terms of accuracy, precision, recall, and F1-score. Additionally, various combinations of RF, XGBoost, and LightGBM with and without the PSO algorithm are also tested. According to the computation results, MLP achieves the highest accuracy for individual algorithms at 0.961089. For hybrid algorithms without the PSO algorithm, a combination of RF and LightGBM performs the best. However, when the PSO algorithm is combined, the hybrid of RF, XGBoost, and LightGBM outperforms all algorithms with an accuracy of 0.972095. Similar trends are observed for precision, where MLP outperforms individual algorithms, and the hybrid of RF and LightGBM performs well without the PSO algorithm. When combined with the PSO algorithm, the proposed algorithm, a hybrid of RF, XGBoost, and LightGBM, still outperforms all algorithms. The results for recall and F1 are consistent with those of accuracy and precision.

Optimization and Analytics for Grid Reliability and Resilience

Invited Session

ENRE: Electricity

Chair: Feng Qiu, Argonne National Laboratory, Lemont, IL, United States

1 - State-of-Charge Estimation across Battery Chemistries: Insights from Unsupervised Domain Adaptation

Mohammad Badfar, Wayne State University, Detroit, MI, United States, Ratna Chinnam, Murat Yildirim

Accurate estimation of the state-of-charge (SOC) in lithium-ion batteries (LIBs) is paramount for the safe operation of battery management systems. Despite the effectiveness of existing SOC estimation methods, their generalization across different battery chemistries and operating conditions remains challenging. Current data-driven approaches necessitate extensive data collection for each battery chemistry and operating condition, leading to a costly and time-consuming process. Hence, there is a critical need to enhance the generalization and adaptability of SOC estimators. In this paper, we propose a novel SOC estimation method based on Regression-based Unsupervised Domain Adaptation. We evaluate the performance of this method in cross-battery and cross-temperature SOC estimation scenarios. Additionally, we conduct a comparative analysis with a widely-used classification-based unsupervised domain adaptation approach. Our findings demonstrate the superiority of the regression-based unsupervised domain adaptation method in achieving accurate SOC estimation for batteries.

2 - Prognostics approach for power asset maintenance

Shijia Zhao, Argonne National Laboratory, Lemont, IL, United States

Aging assets are observed across various power sectors. Almost half of the hydropower plants are exceeding 40 operational years. And we can easily find transformers and power lines exceeding 25 operational years. The changing operational patterns adds to the accelerated degradation. We find it is motivated or even urgent to propose a new generation of models to improve maintenance of power assets.

Periodic maintenance is easy to implement but lacks monitoring and inspection. Diagnostics can discover imminent failure risks but lack the ability to predict asset's failure time. That's why we are proposing prognostics to not only estimate degradation but also provide probability distribution of assets' failure time.

Based on the real-time sensor observations, we build degradation model to provide remaining lifetime distribution, which is used in dynamic maintenance cost model to provide just-in-time maintenance, Not too late, not too early. If we perform maintenance too frequently before actual failure, we waste O&M cost with premature maintenance. But if we perform maintenance too late and cause asset failure, we have to purchase costly replacement due to late maintenance. meaning with the estimates on failure time, we quantify the impacts of premature maintenance versus failure costs. Finally, the maintenance decisions are optimized at fleet level.

3 - Blackstart Power Distribution Grids using Distributed Energy Resources

Zhaoyu Wang, Iowa State University, Ames, IA, United States

This talk will introduce using inverter-based resources (IBRs) to blackstart power distribution grids. While transmission system blackstart has been well studied, power distribution system blackstart is a new topic that recently attracts industry interests thanks to the increasing penetration of IBRs. Because power distribution systems operate very differently than transmission systems, the existing blackstart work cannot be directly implemented. The blackstart of distribution systems requires coordination of grid-forming inverters, grid-following inverters, and intelligent switches, while considering unique characteristics of distribution grid operations, such as the radial topology, the three-phase unbalanced power flow, the stability, and the synchronization. We formulate this problem as a mixed-integer linear program which can be solved efficiently. We will show the performance on a modified IEEE 123-node test system. This talk will also briefly introduce our efforts to build Iowa's first renewable microgrid, which transforms an entire Iowa town to be a microgrid city with the best reliability and resilience.

4 - A generalized framework for resilient optimal sensor placement and fault diagnosis within energy systems

SARA KOHTZ, Binghamton University, Binghamton, NY, United States, Anabel Renteria

Accurate and efficient health monitoring for high power energy systems has become an imperative research area in the field of reliability engineering. Specifically, an optimal sensor network can enhance prognostics of engineering applications across many fields. These include but are not limited to electric vehicles, aircrafts, industrial manufacturing, and many other impactful concentrations. Therefore, determining optimal fault detection frameworks is an essential task. However, due to high cost and safety concerns, there is a scarcity of data from experimental testing and validations for energy systems. Thus, finite element simulation data is a necessity for determining the monitoring system. This study aims to develop a generalizable fault detection framework, which requires techniques that optimize signals processing and sensor placement on a fundamental level. In particular, the proposed method simultaneously determines optimal placement of sensors while training a predictor of faults. In addition, the case where a sensor fails is considered, ensuring one level of resilience for the chosen design. Various search algorithms are implemented to solve the generally applicable mathematical formulation, which utilizes predictor accuracy as the fitness function. The predictor can take on several forms for detection of faults, including a simple K-nearest neighbors, or a complex ensemble learning classifier. The strength of this proposed framework is demonstrated in engineering case studies, including fault detection on electric motors using hall-effect sensors, and partial discharge classification on transformers. Overall, this proposed method converges to a design that has high accuracy for detection of faults, and also satisfies a N-1 redundancy criterion.

Advances in Data-driven Controls for Renewable Dominated Grids

Invited Session

ENRE: Electricity

Chair: Kyung-bin Kwon, Pacific Northwest National Laboratory (PNNL), Richland, United States

Co-Chair: Sayak Mukherjee, Pacific Northwest National Laboratory, Richland, WA, United States

Co-Chair: Hao Zhu, The University of Texas at Austin, Austin, TX, United States

1 - Risk-aware Structured Wide-area Control in Inverter-dominated Power System

Kyung-bin Kwon, Pacific Northwest National Laboratory, Richland, WA, United States

In this research, we develop a risk-aware controller for grid-forming inverters (GFMs) to minimize large frequency oscillations in GFM inverter-dominated power systems. To tackle the high variability from loads/renewables, we incorporate a mean-variance risk constraint into the classical linear quadratic regulator (LQR) formulation for this problem. The risk constraint aims to bound the time-averaged cost of state variability and thus can improve the worst-case performance for large disturbances. The resulting risk-constrained LQR problem is solved through the dual reformulation to a minimax problem, by using a reinforcement learning (RL) method termed as stochastic gradient-descent with max-oracle (SGDmax). In particular, the zero-order policy gradient (ZOPG) approach is used to simplify the gradient estimation using simulated system trajectories. Numerical tests conducted on the IEEE 68-bus system have validated the convergence of our proposed SGDmax for GFM model and corroborate the effectiveness of the risk constraint in improving the worst-case performance while reducing the variability of the overall control cost.

2 - Optimizing Distributed Energy Resources on a Data Budget

Vassilis Kekatos, Virginia Tech, Blacksburg, VA, United States

How much data are really needed to optimally schedule distributed energy resources (DERs)? To decide DER setpoints, a utility may have to solve an optimal power flow (OPF) every few minutes upon collecting values of uncontrollable load demands from hundreds or thousands of nodes. This work exploits redundancies in the data or features feeding the OPF as well as the structure of the OPF per se, to avoid communicating such data deluge and explore the trade-off between compression and grid's performance. The goal is to identify a small subset of critical features and use them to reconstruct a high-dimensional vector to feed the OPF. This task of OPF data selection and reconstruction is posed as a bilevel program wherein the outer level deals with data compression, and the inner level solves multiple instances of the OPF using the compressed data. To forego computationally cumbersome mixed-integer formulations, we put forth a group-Lasso scheme to effect feature selection and solve it via a proximal gradient scheme upon differentiating through the OPF mapping. Numerical tests demonstrate the computational advantage of the proposed scheme over mixed-integer alternatives and showcase the benefit of compressing data while having in mind the effect of compressed OPF data to the OPF solution.

3 - Feedback Optimization of Incentives for Distribution Grid Services

Andrey Bernstein, NREL, Golden, CO, United States

Energy prices and net power injection limitations regulate the operations in distribution grids and typically ensure that operational constraints are met. Nevertheless, unexpected or prolonged abnormal events could undermine the grid's functioning. During contingencies, customers could contribute effectively to sustaining the network by providing services. This talk proposes an incentive mechanism that promotes users' active participation by essentially altering the energy pricing rule. The incentives are modeled via a linear function whose parameters can be computed by the system operator (SO) by solving an optimization problem. Feedback-based optimization algorithms are then proposed to seek optimal incentives by leveraging measurements from the grid, even in the case when the SO does not have a full grid and customer information. Numerical simulations on a standard testbed validate the proposed approach.

4 - Stability-constrained Reinforcement Learning for Power System Control

Yuanyuan Shi, University of California San Diego, La Jolla, CA, United States

The past decade has witnessed success of learning and control methods such as reinforcement learning (RL) in a broad spectrum of applications. As a result, the application of RL in sustainability applications has attracted surging attention recently. Despite the promise, one of the biggest challenges for the deployment of RL in energy systems is the lack of **stability and performance guarantees**. Since energy systems are critical infrastructure, failure to maintain stability can lead to catastrophic consequences.

In this talk, I will present a series of our recent works on developing a stability constrained learning framework that combines policy learning in RL with Lyapunov stability in control to learn policy with formal stability guarantees. Specifically, I will highlight **monotonicity** as a key structure for both power system frequency control and voltage control. I will discuss how can we systematically construct the stability certificates via the Lyapunov approach, derive the structural constraints, and incorporate them into neural network design for guaranteeing stability in power system frequency and voltage control.

5 - Neural ODE-Model Predictive Control for Managing Renewables at the Grid Edge

Qiuhua Huang, Pacific Northwest National Laboratory, Richland, WA, United States, Patrick Salter

High penetration of distributed energy resources (DERs) in distribution systems can lead to fast voltage oscillations and violations issues. Conventional centralized voltage-var optimization and control cannot properly address these issues due to their relatively large control intervals and slow response of the control devices. This presentation introduces a distributed, AI-enabled fast voltage control method to mitigate fast voltage oscillations and violations caused by DERs by smoothing net load variations locally. The work leverages Neural Ordinary Differential Equations (NODE) for modeling residential building thermal dynamics and integrates this model with Model Predictive Control (MPC) within an end-to-end optimization framework to derive the optimal control policy for each residential house. Key findings include the NODE's capability to accurately track thermal dynamics and the success of the combined NODE-MPC in reducing net load variations by aligning HVAC operations with PV generation. Comparative analysis with deep reinforcement learning (DRL)-based centralized voltage control highlights the effectiveness of the NODE-MPC approach.

6 - Leveraging Predictions in Power System Frequency Control: An Adaptive Approach

Wenqi Cui, University of Washington, Seattle, WA, United States, Guanya Shi, Yuanyuan Shi, Baosen Zhang

Ensuring the frequency stability of electric grids with increasing renewable resources is a key problem in power system operations. In recent years, a number of advanced controllers have been designed to optimize frequency control. These controllers, however, almost always assume that the net load in the system remains constant over a sufficiently long time. Given the intermittent and uncertain nature of renewable resources, it is becoming important to explicitly consider net load that is time-varying.

This paper proposes an adaptive approach to frequency control in power systems with significant time-varying net load. We leverage the advances in short-term load forecasting, where the net load in the system can be accurately predicted using weather and other features. We integrate these predictions into the design of adaptive controllers, which can be seamlessly combined with most existing controllers including conventional droop control and emerging neural network-based controllers. We prove that the overall control architecture achieves frequency restoration decentralizedly. Case studies verify that the proposed method improves both transient and frequency-restoration performances compared to existing approaches.

Power Systems Planning and Operation I: Integrating Multivariate Uncertainties

Invited Session

ENRE: Other Energy

Chair: Jordan Kern, North Carolina State University, Durham, NC, United States

1 - Novel Opportunities and Lessons Learned from Pnnl&Rsquo;S Grid Operations, Decarbonization, Energy and Environmental Equity Platform

Nathalie Voisin, Pacific Northwest National Lab., Seattle, WA, United States, The GODEEEP team

Meeting the Paris agreement’s ambitious goal to decarbonize the economy requires a paradigm shift in long-term planning across the entire energy sector. Bulk power grid long-term planning is traditionally performed in three steps: decarbonization roadmap design and scenario analytics, power plant siting and power grid resource adequacy studies, and finally reliability and economics studies. These steps are most often performed independently by different decision-makers (States, power system operators and regulators, and utilities), informed by inconsistent climate and socio-economics datasets across stakeholders. Consistent and accessible datasets and tools are critical to support the energy sector in their individual long-term planning towards overarching recommendations for resource adequacy, reliability, and cost efficiency. PNNL’s Grid Operations, Decarbonization, Environmental and Energy Equity Platform (GODEEEP) is a unique high-resolution, modular, and integrated modeling capability that evaluates the investment, operational, and equity challenges of alternative strategies to decarbonize the U.S. economy by 2050. This presentation will focus on the readily available tools, datasets and ways they can be leveraged through the lenses of end-use cases. This presentation will also provide the lessons learned and remaining gaps to support the communities in climate and equity informed energy plans and investments.

2 - Fairness in Post-Disaster Power Restoration

Benjamin Rachunok, North Carolina State University, Raleigh, NC, United States, Ignacio Sepulveda

The power grid Is essential to maintaining the basic functioning of a community. The frequency and intensity of extreme weather events has increased significantly worldwide and has been translated into longer, and more frequent power outages, causing social and economic damages. Evidence from previous restoration schedules has shown a significant disparity in the extent and duration of power outages experienced by low-income and minority groups, and rural communities. This reveals the necessity of including fairness into power restoration planning, translating equity policies into quantitative metrics and results. Current restoration strategies are based on experience, cost reduction, community resilience (time without power-based), or priority-based considering critical infrastructure (hospitals, fire stations, etc.), without considering customers’ characteristics. In this research, we address the power restoration planning problem for a transmission network considering customers’ vulnerability, captured by the CDC/ATSDR’s Social Vulnerability Index. In this problem, we dispatch a set of homogeneous repair crews to fix damaged components, in order to restore the power in an equitable manner considering operational constraints. The problem is modeled as a Mixed-Integer Linear Programming model, where equity is included in the objective function, testing different fairness perspectives. For each fairness perspective, the price of fairness is also computed in order to determine how expensive is the implementation of the corresponding strategy.

3 - Grace Foreseer: a Probabilistic Forecast Generator for Stochastic Unit Commitment

Dalia Patino-Echeverri, Duke University, Durham, NC, United States, Dimitrios Floros, Wei Wang, Mauricio Hernandez, Jordan Kern, Xiaodong Zhang

Increased probability of extreme weather events and ongoing and planned increases in the penetration of Variable Renewable Energy (VRE) resources in electric power systems highlight the need for improved uncertainty characterization and commitment and dispatch methods that account for such uncertainty.

We propose the GACE FORESEER which generates high quality Probabilistic Forecasts of weather variables, load, and variable renewable energy, for use in a Stochastic Unit Commitment (SUC). The outputs of the FORESEER are ensembles of time-series each with the same probability of occurrence. Each multivariable time series represents a plausible trajectory for weather variables, load, and wind solar energy production for each hour of a week-long planning horizon, in a specific geographical area.

Acknowledging that quality probabilistic forecasts for SUC cannot be presented as quantile trajectories -as often presented, with unrealistic temporal patterns of electricity demand (i.e., load) and/or renewable generation, where all hours have a load in the same percentile, the PFG forecasts are realistic as assessed by six metrics. These metrics focus on the Probability Distribution Function, the Autocorrelation Function, the geographic and variable cross correlations, the forecast errors, and the Continuous Ranked Probability Score.

4 - Impacts of Climatic and Socioeconomic Uncertainties on Net-Zero Power Systems Reliability: a Case Study from New York State

Vivek Srikrishnan, Cornell University, Ithaca, NY, United States

How do climatic and socioeconomic uncertainties impact the reliability of net-zero power systems? In this talk, I will provide an overview of recent research into how climatic, socioeconomic, and technological uncertainties jointly impact the performance of the planned future New York State (NYS) power system. NYS has one of the most ambitious electric power system decarbonization targets in the world, requiring net-zero emissions by 2040. To meet this goal, the New York Climate Action Council has created a scoping plan to expand the amount of renewable generation and storage to supplement hydropower from the Great Lakes. Stress-testing this plan against a variety of future climate and electrification scenarios provides insights into the reliability and vulnerability of decarbonizing and decarbonized power systems. I will highlight the impacts of these uncertainties on prices and load shedding, and share challenges posed by available climate data products for this stress testing.

5 - Balancing Accuracy and Computing Costs: Can We use Heuristics to Solve a Large-Scale Unit Commitment Problem?

Phumthep Bunnak, Cornell University, Ithaca, NY, United States, Stefano Coniglio, Stefano Galelli

Power system models have become increasingly larger and more complex, driven by use cases such as uncertainty analysis and multi-sectoral integration. These models are often run multiple times with different parameters, making runtime a bottleneck in the design of computational experiments. Currently, energy system modelers typically trade model accuracy with tractability by simplifying temporal, spatial, or technological dimensions. By leveraging the mathematical formulation of power system models, in this case a unit commitment problem, heuristics may offer an alternative pathway to reduce model runtime while maintaining an accurate system representation. Here, we explore this direction and contribute two novel computational frameworks to solve large-scale unit commitment problems: a rounding heuristic and a modified Dantzig-Wolfe decomposition. Computational experiments on country-scale grids reveal a speed-up reaching up to 10x while maintaining an optimality gap lower than 1%. The rounding heuristic proves to be highly scalable with problem size. Although runtime and solution quality may vary, these heuristics are not specific to any particular unit commitment problem.

6 - Deep Uncertainty and Deep Decarbonization: Scenario Discovery of Global Energy Transitions

Jacob Wessel, Tufts University, Medford, MA, United States, Gokul Iyer, Jonathan Lamontagne, Thomas Wild, Yang Ou, Haewon McJeon

Deep decarbonization is a primary objective for energy systems planners striving to meet national and global climate goals. Objectives, pledges, and obligations set forth by the Paris Agreement in both the short- (2030) and medium-term (2050-2060) pose a complex planning problem subject to deep uncertainty across multiple interconnected systems. Exploratory modeling analyses systematically mapping a wide outcome space through large scenario ensembles are needed to reveal robust strategies for decisionmakers to meet decarbonization goals. This study applies scenario discovery to 5,760 model realizations generated using a global multi-sector climate-economic model. The large ensemble systematically varies eleven energy-related uncertainties, including techno-economic parameters, institutional factors, and national mitigation pledges, among others. This broad collection of future states of the world is used to characterize the impacts of various uncertainties on national and global deep decarbonization pathways. Results show that energy transitions may be globally consistent while regionally disparate, as measured by multiple common energy system metrics. Larger economies and developing regions experience more severe economic outcomes, which can be exacerbated by regional investment risk throughout a wide uncertainty space. Further, the role of different CO_2 removal options in meeting mitigation pledges can vary widely across regions, though the global scale of CO_2 removal principally determines the budget for continued energy system emissions. Previous large-ensemble work has not (to the authors' knowledge) combined such a framework with national emissions pledges or institutional factors. This study highlights advantages of using scenario discovery for decision support as countries design strategies to meet future goals.

Recent Advances in Stochastic and Robust Optimization

Invited Session

Computing Society

Chair: Haoming Shen, University of Arkansas, Fayetteville, AR, United States

1 - Two-Stage Distributionally Robust Optimization for Service Region Design in Crowdsourced Delivery

Aliaa Alnaggar, Toronto Metropolitan University, Toronto, ON, Canada, Merve Bodur

We consider a service region planning problem faced by a crowdsourced delivery platform where drivers are commuters who are willing to deviate from their original routes to a make a delivery in exchange for a compensation. The availability of drivers and service demand are uncertain, and it is difficult to estimate their probability distributions due to the absence of service history. To mitigate the effects of data ambiguity, we propose a two-stage distributionally robust optimization (DRO) model. The first stage selects which nodes to offer service in, while the second stage matches drivers and orders after uncertainty is realized. We derive an exact reformulation of the DRO model and develop a monolithic approximation based on a convex relaxation of the subproblem. We further strengthen the proposed approximation by a set of valid inequalities inspired by the linearization reformulation technique. The benefit of the proposed approach for service region design in crowdsourced delivery is demonstrated through numerical experiments.

2 - Residuals-Based Contextual Distributionally Robust Optimization with Decision-Dependent Uncertainty

Zoey Zhu, The Ohio State University, Columbus, OH, United States, Xian Yu, Guzin Bayraksan

3 - Value of Stochastic Solution with Right-Hand Side Uncertainty

Haoming Shen, University of Arkansas, Fayetteville, AR, United States

We revisit the value of stochastic solution (VSS) in the context of distributional ambiguity. When uncertainty arises from the right-hand side of a two-stage stochastic program, we investigate VSS's upper and lower bounds using distributionally robust and optimistic optimization. Because these bounds are NP-hard to compute exactly, we derive tractable yet tight relaxations for them and demonstrate their effectiveness through numerical experiments.

4 - Risk-Averse Reinforcement Learning for Economic Dispatch with Uncertain Demand Response

Bo Zhou, University of Michigan, Ann Arbor, MI, United States, Ruiwei Jiang, Siqian Shen, Xian Yu

We study risk-averse reinforcement learning (RL) for real-time economic dispatch with uncertain demand response (DR). The proposed risk-averse RL controls dynamic risk of a sequence of rewards in infinite-horizon Markov Decision Processes (MDPs), where we adapt the Expected Conditional Risk Measures (ECRMs) and prove time consistency. Using a combination of expectation and conditional value-at-risk (CVaR), we reformulate the risk-averse MDP as a risk-neutral counterpart with augmented action space and manipulation on the immediate rewards. We further prove that the Bellman operator is a contraction mapping, which guarantees the convergence of any value-based RL algorithms. Accordingly, we develop a risk-averse deep Q-learning framework to reduce variance and enhance solution robustness, and demonstrate our methods for real-time economic dispatch with uncertain DR on IEEE systems.

Modern Results in Computational Statistics

Invited Session

Computing Society

Chair: Ilias Zadik, Yale, New Haven, CT, United States

1 - Deterministic Algorithms for Continuous Approximation Problems

Devin Smedira, Massachusetts Institute of Technology, Cambridge, MA, United States, David Gamarnik

We explore the applications of the correlation decay technique to design deterministic approximation algorithms for continuous problems with a bounded degree structure. We construct a quasi-polynomial time deterministic approximation algorithm for computing the volume of an independent set polytope with restrictions. Randomized polynomial time approximation algorithms for computing the volume of a convex body have been known now for several decades, but the corresponding deterministic counterparts are not available, and our algorithm is the first of this kind. The class of polytopes for which our algorithm applies arises as linear programming relaxation of the independent set problem with an additional restriction on each variable dependent on the maximal degree of the graph. We apply the correlation decay method to the natural discretization of this problem. We will also show how similar techniques can be applied to approximating the integral of classes of functions defined with respect to bounded degree graphical models.

2 - Power of two matrices of spectral algorithms for community detection

Souvik Dhara, Purdue University, West Lafayette, IN, United States

Spectral algorithms are some of the main tools in optimization and inference problems on graphs. In this talk, we discuss the power of spectral algorithms using two matrices in a simple graph partitioning problem with censored edges. It is shown that any spectral algorithm based on one matrix is suboptimal for most choices of the parameters, while spectral algorithms based on two matrices are optimal.

Based on joint work with Julia Gaudio, Elchanan Mossel, Colin Sandon

3 - The Low-Temperature MCMC threshold for sparse tensor PCA

Ilias Zadik, Yale, New Haven, CT, United States

Over the last years, there has been a significant amount of work studying the power of specific classes of computationally efficient estimators for multiple statistical models, including the class of low-degree polynomials, spectral methods and others. Despite that, our understanding of the important class in applications of MCMC methods remains quite poorly understood. For instance, for many models of interest the performance of even zero-temperature (greedy-like) MCMC methods is elusive.

I will describe you a recent result that that we fully characterize the performance of low-temperature MCMC methods for the case of the sparse tensor PCA model. In particular, we discover that it the required signal to noise ratio requires for these MCMC methods to work is significantly higher than the performance of the best known polynomial-time estimator.

4 - Smoothed Analysis for Learning Concepts with Low Intrinsic Dimension

Vasilis Kontonis, University of Texas at Austin, Austin, TX, United States, Gautam Chandrasekaran, Adam Klivans, Raghu Meka, Konstantinos Stavropoulos

In the well-studied agnostic model of learning, the goal of a learner-- given examples from an arbitrary joint distribution on $\mathbb{R}^d \times \{\pm 1\}$-- is to output a hypothesis that is competitive (to within ϵ) of the best fitting concept from some class. In order to escape strong hardness results for learning even simple concept classes in this model, we introduce a smoothed analysis framework where we require a learner to compete only with the best classifier that is robust to small random Gaussian perturbation.

This subtle change allows us to give a wide array of learning results for any concept that (1) depends on a low-dimensional subspace (aka multi-index model) and (2) has a bounded Gaussian surface area. This class includes functions of halfspaces and (low-dimensional) convex sets, cases that are only known to be learnable in non-smoothed settings with respect to highly structured distributions such as Gaussians.

Perhaps surprisingly, our analysis also yields new results for traditional non-smoothed frameworks such as learning with margin. In particular, we obtain the first algorithm for agnostically learning intersections of k-halfspaces in time $k^{\poly(\frac{\log k}{\epsilon \gamma}) }$ where γ is the margin parameter.
Before our work, the best-known runtime was exponential in k.

Summit - Ballroom 3

Omega Rho Keynote Steve Eppinger

Plenary/Keynote Session

Keynote

Chair: Jose Correa, Universidad de Chile, Santiago, Chile

1 - Adventures in Engineering Management

Steven Eppinger, Massachusetts Institute of Technology, Cambridge, MA, United States

There are many interesting problems in engineering management for which network modeling and management science methods can be usefully applied - particularly where complex systems are involved. In this Omega Rho Distinguished Lecture, I will describe some problems addressed using Design Structure Matrix methods, challenges of Agile development for complex systems, and more..

Summit - Ballroom 2

The Importance of Lived Experience for Better, Smarter OR Models to Disrupt Sex Trafficking

Plenary/Keynote Session

Keynote

Chair: Maria Mayorga, North Carolina State University, Raleigh

1 - The Importance of Lived Experience for Better, Smarter OR Models to Disrupt Sex Trafficking

Thomas Sharkey, Clemson University, Clemson, SC, United States

Given the complexity and range of experiences in human trafficking, research and practice in this space has the potential for unintended consequences. Even well-meaning research and action can cause great harms if based on fuzzy conceptualization, overgeneralizations, or incomplete data. This talk will demonstrate the importance of including experts with lived experience, commonly referred to as survivors, in creating OR approaches to disrupt sex trafficking. It will show how our conceptualization of sex trafficking became better (more accurate, attuned to context, and actionable) and how our OR models and analysis became smarter because of our inclusion of experts with lived experience as research partners. The talk will then discuss how the OR and analytics community can include people with lived experience in our community's efforts to help disrupt sex trafficking.

1 - From Lotteries to Optimal Decision Making: Operations Research and the Theory of Moments

Chung Piaw Teo, National University of Singapore Business School, Singapore, Singapore

Lottery games, with their complex probabilistic structures and significant financial stakes, provide a fertile playground for Operations Research (OR) researchers. This talk explores rich opportunities for applying advanced OR techniques to optimize various aspects of lottery operations, from ticket sales to payout management, and illustrates the broader implications for decision making in related fields. Through various real life case studies, we demonstrate how the study of lottery games can yield insights into human behavior, statistical anomalies, and effective risk management strategies. In particular, we show mean-variance analysis, a core concept within the theory of moments, can be a powerful method in decision making within this sector. This method evaluates the trade-off between risk and return, providing a structured and quantitative approach to optimize decisions under uncertainty.
We also develop a general framework for the “picking winners” problem, aiming to select a small pool of candidate solutions to maximize the chances that one will perform exceedingly well ina combinatorial optimization problem, under a linear and additive random payoff function. This problem is formulated using a two-stage distributionally robust model with a mixed 0-1 semidefinite program, leveraging the Theory of Moments. This approach allows us to exploit the diversification effect to improve the chances of achieving a high ex-post payoff.

Applications of this framework in fields such as revenue management (offer construction) and fraud detection (credit rating) will be presented. Additionally, we demonstrate how this framework is connected to the field of explainable AI, enhancing transparency and trust in the decision-making process.

Recent Advances in Human – AI Interactions

Invited Session

Service Science

Chair: Agni Orfanoudaki, Oxford University, Oxford, OX26SQ, United Kingdom

1 - Algorithmic Assistance with Recommendation-Dependent Preferences

Jann Spiess, Stanford GSB, Stanford, CA, United States, Bryce Mclaughlin

When an algorithm provides risk assessments, we typically think of them as helpful inputs to human decisions, such as when risk scores are presented to judges or doctors. However, a decision-maker may not only react to the information provided by the algorithm. The decision-maker may also view the algorithmic recommendation as a default action, making it costly for them to deviate, such as when a judge is reluctant to overrule a high-risk assessment for a defendant or a doctor fears the consequences of deviating from recommended procedures. To address such unintended consequences of algorithmic assistance, we propose a principal-agent model of joint human-machine decision-making. Within this model, we consider the effect and design of algorithmic recommendations when they affect choices not just by shifting beliefs, but also by altering preferences. We motivate this assumption from institutional factors, such as a desire to avoid audits, as well as from well-established models in behavioral science that predict loss aversion relative to a reference point, which here is set by the algorithm. We show that recommendation-dependent preferences create inefficiencies where the decision-maker is overly responsive to the recommendation. As a potential remedy, we discuss algorithms that strategically withhold recommendations, and show how they can improve the quality of final decisions.

2 - Human-AI Interactions and Societal Pitfalls

Jian Gao, UCLA Anderson School of Management, Los Angeles, CA, United States, Francisco Castro, Sebastien Martin

When working with generative artificial intelligence (AI), users may see productivity gains, but the AI-generated content may not match their preferences exactly. To study this effect, we introduce a Bayesian framework in which heterogeneous users choose how much information to share with the AI, facing a trade-off between output fidelity and communication cost. We show that the interplay between these individual-level decisions and AI training may lead to societal challenges. Outputs may become more homogenized, especially when the AI is trained on AI-generated content. And any AI bias may become societal bias. A solution to the homogenization and bias issues is to improve human-AI interactions, enabling personalized outputs without sacrificing productivity.

3 - Automated Feature Extraction for the Sts National Database: the Impact of Artificial Intelligence

Periklis Savvas Petridis, Massachussetts Institute of Technology, Cambridge, MA, United States, George Margaritis, Agni Orfanoudaki, Dimitris Bertsimas

Cardiothoracic surgery departments and clinics in the US rely on central agencies, such as the Society of Thoracic Surgeons (STS), to evaluate their operational performance compared to their peer institutions. Specifically, 97% of U.S. adult cardiac surgery programs collaborate and transfer their patient data to the STS National Database for quality improvement and risk assessment. However, as patient records primarily consist of unstructured text reports, such data transfers involve a large operational overhead, requiring manual data extraction by teams of experienced data managers. Utilizing recent breakthroughs in Natural Language Processing, we propose an end-to-end machine learning pipeline that automatically extracts all patient data (either structured or unstructured) from multiple sources, over multiple patient visits, and for multiple target outcomes. Our pipeline can be extended to new sources or outcomes, as hospitals may use different data conventions from each other. Preliminary results on Massachusetts General Hospital data show promise and our methodology achieves up to 98% AUC in common diagnoses and up to 85-95% in more challenging ones. We believe using an automated pipeline for data extraction has four benefits: i) reduce operational overhead and costs for institutions when transferring their data, ii) increase data consistency and quality, while reducing variation from human errors, iii) allow institutions to transfer even richer data that would otherwise require additional human effort, and iv) create a unified framework for end-to-end medical predictions and diagnoses from any type and format of patient medical reports.

4 - Learning the Minimal Representation of a Continuous State Space Mdp from Transition Data

Omar Skali, QuantumBlack, Boston, MA, United States

We propose a novel framework for learning a concise MDP model of a continuous state space dynamic system from observed transition data. Our approach relies on partitioning the system's feature space into regions constituting states of a finite deterministic MDP representing the system. We introduce an in-sample property on partitions of the feature space we name coherence and show that if the class of possible partitions is of finite VC dimension, any coherent partition with the transition data converges to the minimal representation of the system with provable finite-sample PAC convergence guarantees. This theoretical insight motivates our Minimal Representation Learning (MRL) algorithm.

5 - Does Robot-Assisted Surgery improve healthcare delivery?

Sung Joo Kim, Purdue University, West Lafayette, IN, United States, Jianing Ding, Susan Lu

We investigate the role of an emerging AI-based clinical treatment method, robot-assisted surgery (RAS), in transforming the healthcare delivery. In this study, we first examine the effect of RAS on clinical outcomes. Further, investigating the RAS implementation, we show the synergy of RAS implementation in alleviating healthcare racial disparity.

Domain Knowledge in Learning Models: Relevance in Big Data Era

Invited Session

Quality, Statistics and Reliability

Chair: Raghav Gnanasambandam, Virginia Tech, Blacksburg, VA, 24060, United States

Co-Chair: Bo Shen, New Jersey Institute of Technology, Newark, NJ, United States

1 - Ml & Domain Knowledge with Applications in Manufacturing

Mengfei Chen, Rutgers University, Piscataway, NJ, United States, Weihong Guo

While deep learning algorithms in additive manufacturing have demonstrated efficacy in analyzing complex, massive data, the deployment of deep neural networks necessitates substantial datasets for training, posing challenges in real manufacturing scenarios. The limited availability of defect data leads to imbalanced datasets, especially in small-batch or one-of-a-kind manufacturing scenarios, significantly limiting the performance of predictive models. While dealing with limited data from one type of defect is already non-trivial, the issue of imbalanced dataset becomes even more challenging when multiple defects are unbalanced (some defects occur more than others). To address these challenges, this study introduces a conditional DCGAN-based data augmentation method that ensures the physical validity of synthetic in-process sensor data. The model incorporates domain knowledge such as layer information, temperature distribution, and the shape of the melt pool. Physics constraints are integrated into the custom architecture of the generator, and penalty terms are added to the loss function to prevent the production of outputs that violate physics constraints. This approach not only reduces reliance on historical data but also enhances defect prediction accuracy.

2 - Sparsest: Exploiting Data Sparsity in Spatiotemporal Modeling and Prediction

Junfeng Wu, Rensselaer Polytechnic Institute, Troy, NY, United States, Yinan Wang

Spatiotemporal data mining has a wide range of applications in modeling and predicting various complex physical systems (CPS), i.e., transportation, manufacturing, healthcare, etc. Among all the proposed methods, the Convolutional Long-Short Term Memory (ConvLSTM) has proved to be generalizable and extendable in different applications. However, ConvLSTM and its variants are computationally expensive, which makes it inapplicable in edge devices with limited computational resources. With the emerging need for edge computing in CPS, efficient AI is essential to reduce the computational cost while preserving the model performance. Common methods of efficient AI are developed to reduce model redundancy (i.e., model pruning, etc.). However, model redundancy is limited in spatiotemporal data mining as the embedded dependencies are complex and hard to capture. Instead, there is a fair level of data redundancy, which has been largely overlooked in existing research. Using the sequence of images as an example, (1) the informative pixels at each frame are usually spatially sparse (i.e., with a fixed background), and (2) the informative features in the first-order difference of two adjacent images are possibly sparse due to the slow temporal evolvement. Therefore, we develop a novel efficient ConvLSTM that pioneering exploits the sparsity of informative features. More specifically, the sparse convolution and the Delta algorithm are incorporated to exploit the spatial sparsity at each single time step and the sparsity in the first-order difference over a sequence, respectively. The experiment demonstrates that our proposed methods can achieve comparable performance to the original ConvLSTM with reduced computational complexity.

3 - Sequential Optimization Based on a Networked System

Siqin Yang, Arizona State University, Tempe, AZ, United States, Hao Yan

Composite Bayesian optimization that leverages insights from the internal components of objectives has demonstrated excellent performance across various applications. Using directed acyclic graphs, these networked systems can be optimized sequentially. For instance, an additive manufacturing process can be mapped as a sequential printing process with output from last layer would serve as input for the future layer. This presentation will concentrate on sequential optimization of the process parameters for each layer, employing rollout as a value approximation to estimate the reward for each action. By utilizing internal components in our graph models, we propose a method for making dynamic decisions applicable to various scenarios.

4 - Physics-Guided Auto-Regressive Neural Network with eXogenous Inputs

Xinchao Liu, Georgia Institute of Technology, Atlanta, GA, United States, Yifeng Wang, Chuck Zhang, Xiao Liu

It is challenging to train a physics-guided neural network with time-varying exogenous inputs for transient dynamical systems. In this work, we propose a novel approach, Physics-Guided Auto-Regressive Neural Network with eXogenous Inputs, to learn the temporal evolution of system states controlled by time-varying exogenous inputs such as heat sources and pollution releases.

Advanced Statistical Models and Decision Making

Contributed Session

Chair: Wenlan Xie, The University of Sydney, Sydney, N/A, Australia

1 - Quickest Change Detection in Multi-Stream Unnormalized and Score-Based Statistical Models

Wuxia chen, University of Pittsburgh, Pittsburgh, PA, United States, Sean Moushegian, Taposh Banerjee, Vahid Tarokh

This paper introduces an approach to mult-stream quickest change detection for unnormalized and score-based statistical models. Traditional optimal algorithms in the quickest change detection literature require explicit pre-change and post-change distributions to calculate the likelihood ratio of the observations, acquiring which could be computationally costly and sometimes even not feasible for complex machine learning models. To address these challenges, we propose the min-SCUSUM method, which is a Hyvarinen Score-based algorithm. The Hyvarinen Score can be calculated for unnormalized and score-based models. We provide delay and false alarm analysis of the proposed algorithm and show that the asymptotic performance of the algorithm depends on the Fisher divergence between the pre- and post-change distributions.

2 - Connections to Consumption: Fusing Network Analysis and Machine Learning for Premium Wine Market Forecasts

Bryan Boots, University of Missouri-Kansas City, Kansas City, MO, United States

This study develops a predictive model for estimating global demand for Chilean wine, utilizing a combination of classical machine learning methods, natural language processing (NLP), and network (graph) methods. The ensemble and nested models draw from diverse data sources, including a structured dataset of wine exports from Chile, unstructured text-based product reviews, insights derived from network/graph models that represent complex market interactions, and macroeconomic and demographic data.

The methodology integrates these heterogeneous data forms to understand factors related to global demand for Chilean wine. Machine learning algorithms predict sales volumes, while NLP techniques analyze sentiments, topics, and trends from customer reviews to gauge consumer preferences across national markets. Network methods elucidate the relationships between market actors and their impact on wine sales.

The model’s robustness is tested through against historical data. In an industry where long-term capital investments are crucial – newly-planted grapevines take at least three years to produce commercially viable grapes, and up to ten years for a new vineyard to reach breakeven – even small improvements in demand forecasting can significantly impact business outcomes. This model aids stakeholders in strategic planning and inventory management and offers insights for sales and marketing professionals in competitive B2C or B2B2C environments.

By advancing hybrid analytical methods in market demand forecasting, this work contributes to consumer analytics, demonstrating how integrated data-driven approaches can enhance the understanding of consumer behavior and market dynamics. This approach provides a novel contribution to both the academic literature and practical applications in market demand forecasting.

3 - Classification of Unbounded Data by Gaussian Mixture Models via deep ReLU Networks

Tian-Yi Zhou, Georgia Institute of Technology, Atlanta, GA, United States, Xiaoming Huo

This paper studies the binary classification of unbounded data from R^d generated under Gaussian Mixture Models (GMMs) using deep ReLU neural networks. We obtain — for the first time — non-asymptotic upper bounds and convergence rates of the excess risk (excess misclassification error) for the classification without restrictions on model parameters. While the majority of existing generalization analysis of classification algorithms relies on a bounded domain, we consider an unbounded domain by leveraging the analyticity and fast decay of Gaussian distributions. To facilitate our analysis, we give a novel approximation error bound for general analytic functions using ReLU networks, which may be of independent interest. Gaussian distributions can be adopted nicely to model data arising in applications, e.g., speeches, images, and texts; our results provide a theoretical verification of the observed efficiency of deep neural networks in practical classification problems.

4 - Balancing the Costs and Benefits of Resilience-based Decision Making

, Weimar Ardila, Alex Savachkin, Daniel Romero, Jose Navarro

Most resilience models often prioritize measuring resilience using static, deterministic optimization techniques. However, robust post-disruption responses in social-physical (SP) systems require a focus on both rapid recovery and proactive mitigation of economic loss.} This paper proposes a stochastic dynamic optimization model based on an infinite horizon Continuous-Time Markov Decision Process (CTMDP) to balance the intervention costs and reduce the total recovery time ensuing from a disruption of an SP system. We aim to provide a model that can facilitate its application to different disruption scenarios. Our state-space formulation of the recovery process uses discrete performance intervals, whereby actions and resulting rewards/costs are related to investment resources, which govern state transitions. We illustrate the model via a testbed based on the 2010 Northern Colombia Dique Canal breach. Our results show that the optimal policy reduced the recovery time and restoration investment by approximately 40% and 10%, respectively, compared to the efficiency of government interventions. The proposed model features dynamic control of recovery resources and considers the costs of resilience assurance. The model can inform policymakers of ways to improve system resilience using balanced disruption recovery strategies.

5 - Guiding Smarter Decisions: AI-Driven Framework for Predicting Movie Success and Analyzing Dissemination Patterns

Wenlan Xie, The University of Sydney, Sydney, Australia, Haowen Tian

This study introduces a robust analytical framework integrating three advanced computational models to predict and analyze movie success dynamics comprehensively. Utilizing a dataset of 2,400 top-ranked IMDb movies spanning 2007 to 2024, alongside 270,000 reviews obtained through web scraping, this research employs a pre-trained Transformer model to perform sentiment analysis on movie reviews. These sentiments are subsequently processed through a Susceptible-Infectious-Recovered (SIR) model, effectively forecasting the dissemination rates of films. The integration of the SIR model, which has been demonstrated to enhance predictive capabilities by 85%, plays a pivotal role in developing unique dissemination features and vital inputs for a subsequent multi-task learning (MTL) model.

The MTL model leverages these inputs to predict movie success and initial box office revenue with refined accuracy, benefitting from the joint learning process that integrates structured data with dissemination metrics. This comprehensive modelling approach offers profound insights into the interrelations between consumer sentiment, societal influence, and market performance and significantly advances the film industry's predictive analytics capabilities. The rigorous integration of these models emphasizes the value of multidimensional analysis. It sets a new standard for predictive accuracy in film industry analytics, enabling stakeholders to make more informed decisions regarding marketing strategies, content alignment, and financial planning. This framework exemplifies the transformative potential of machine learning in enhancing industry-specific decision-making and academic rigour in social sciences research.

Models for Corporate Decisions

Contributed Session

Chair: Yuanzhe Ma, Columbia University, New York, NY, United States

1 - Speed is the Essence of Warfare: the Impact of Rivalry on New Product Launches After An Innovative Shock

Fernando Campayo-Sanchez, University of Alicante, San Vicente del Raspeig, Spain, Francisco J. Mas-Ruiz, Juan Luis Nicolau

In this paper, we examine how product marketing decisions following an innovation shock may be affected by rivalry. We conceptualize innovation shock as the launch of a new innovative product design whose sales exceed the firm's expectations. To explain the entrant's reaction (especially in terms of speed of entry), we use product-level competitive comparisons disclosed by the companies. First, our research focuses on the awareness-motivation-capability (AMC) paradigm, anchored in the competitive dynamics literature. With competitive comparisons (whether at the visual, mechanical, or equipment level), incumbents try to convince consumers that their products are better than the products that entrants intend to market. In this scenario, the first hypothesis argues that an entrant will introduce a product earlier in a post-shock market position when it receives a comparative attack from an incumbent. The second hypothesis posits that, in a post-shock market, firms are more likely to accelerate the commercialization of their products when they develop an intentional cannibalization strategy (by disclosing competitive comparisons between their own products). To conduct the study, we analyzed the Spanish electric vehicle market between 2003 (the year in which the innovation shock occurred, coinciding with the commercialization of the second-generation Toyota Prius) and 2017. At the methodological level, we use mixed-effects Cox regression models and multinomial logit models with random coefficients to control for the existence of unobserved heterogeneity. Our results support the relationships assumed in the hypotheses and represent a breakthrough in the literature linked to competitive dynamics, social comparison, and intra-firm competition.

2 - Measuring and managing (un)sustainable workload under digitization: An activity analysis-based job demands-resources model

Ahmed-Youssef Oukassou, KU Leuven, Lille, France, Marijn Verschelde, Raluca Parvulescu

In this paper, we bridge the psychological Job Demands & Resources (JD-R) literature with the operations literature on activity analysis. The JD-R model provides a comprehensive framework, categorizing risk factors associated with different occupations. On one hand, resources positively affect performance, while on the other hand, demands relate to work conditions. Understanding the health impairment process (strain due to excessive demands) and the motivational process (resource-driven well-being enhancement) is essential in defining a sustainable level of workload. We apply a multidimensional nonparametric activity analysis on the JD-R model, to assess the relation between resources, demands, and mental well-being of employees. Using event-level data of railway control room operators, we construct a multidimensional JDR indicator for digital production, which we empirically validate by using proxies for operational risk and employee well-being.

3 - Does disruptive preference matter for team innovation? The conditional effects of compiled disruptive preference in scientific research teams

Xuansheng Wang, Renmin University of China, Beijing, China, People's Republic of, Qihan Yang, Zhiyang Liu, Jia Liu, Lifan Chen

This paper explores how team members' disruptive preference(DP) compiles to contribute to team innovation. Based on the interactional approach, we argue that team composition(compiled individual DP) affects innovation outcomes, and this effect differs between high-impact teams and low-impact teams. Using an open data set covering over 134M scientific publications, we conduct 2 studies to examine our hypotheses. Study 1 analyzes 184,811 research teams with papers in Nature, Science, PNAS or PLOS ONE published between 1900 and 2020, focusing on the effects of team mean DP on innovation outcomes and the moderating role of team influence. Study 2 examines 17,793 research teams that include Nobel Prize laureates, using polynomial regression and response surface analysis to investigate the effect of laureate-member DP congruence on innovation outcomes. The findings suggest: (1) team mean DP negatively affects outcome influence and positively affects outcome disruption. (2) Team influence positively moderates the relationship between mean DP and outcome influence, yet it negatively moderates the relationship between mean DP and outcome disruption. (3) In general, laureate-member DP congruence positively affects outcome influence and outcome disruption. (4) To high-impact teams, the congruence positively affects outcome influence; to low-impact teams, the congruence negatively affects outcome influence. This paper provides a novel perspective on team formation, emphasizing the role of compiled members' disruptive preference, and offers practical guidance for individuals with high innovative potential to assemble effective teams.

4 - The Distributional Effects of "Fulfilled by Amazon" (Fba)

Yuanzhe Ma, Columbia University, New York, NY, United States, Garud Iyengar, Thomas Rivera, Fahad Saleh, Jay Sethuraman

We provide an economic model of an e-commerce retail platform (e.g., Amazon) that offers a fulfillment service (e.g., "Fulfilled By Amazon") to merchants that sell on its platform. We demonstrate that the introduction of such a service generates disparate impacts on the different platform participants. In particular, while such a service benefits low service quality merchants and consumers, it reduces welfare for high service quality merchants. We compare the economic implications of the fulfillment service when it is introduced by the platform as opposed to when it is introduced by an independent logistics company. We show that the distributional welfare effects are more pronounced when the platform provides the fulfillment service thereby demonstrating the impact that dual ownership of the platform and fulfillment service has on participant welfare.

5 - Predicting Customer Lifetime using Machine Learning at Expedia Group

Alireza Inanlouganji, Expedia Group, Kirkland, WA, United States

Customer Lifetime Value (CLV) represents the customer's future cash flows over a long-term horizon, such as one year and beyond. Having the ability to estimate the future value of each customer enables businesses to make better decisions about customer acquisition, retention, incentives, marketing communications, long-term investments, and growth.

In this talk, we describe development, implementation and deployment of the CLV prediction models on the Unified Machine Learning platform at Expedia Group. The models are re-trained monthly and future value predictions for hundreds of millions of customers are updated daily and are consumed by business units and teams within Expedia Group.

New Methods for Combinatorial Problems

Contributed Session

Chair: Raunak Sengupta, University of Illinois, Urbana Champaign, Urbana, IL, United States

1 - Estimating Optimal Solutions for the Knapsack Problem Through Regression and Machine Learning

Hugo Mainguy, University of Maryland, College Park, MD, United States, Bruce Golden, Luca Bertazzi

As with other NP-Hard problems, the knapsack problem can be computationally expensive to solve to optimality. Faced with this problem, we develop approaches to obtain estimated optimal solution values that are both very close to the optimal value and efficiently computable. Specifically, while leveraging multiple diverse datasets of various complexities, we find that, in line with previous work, we can obtain good accuracy using a linear regression model which includes the mean and standard deviation of simulations obtained using a randomized greedy heuristic as predictors. We can also include predictors based on the linear programming relaxation and a feasible solution of the integer program, and we can improve accuracy while maintaining reasonable computation times by applying random forest and neural network methods. The results are especially encouraging for more difficult datasets, where traditional estimation methods tend to produce disappointing results.

2 - Valid inequalities for cardinality constrained knapsack problems

Jinhak Kim, Ajou University, Suwon, Korea, Republic of

We study a continuous knapsack problem with an additional constraint that the number of nonzero components of the decision variable is no more than a fixed positive integer. This seemingly simple optimization problem is in fact NP-hard. When a branching scheme is applied to solve the problem to optimality, tight linear relaxations may reduce the number of enumeration and improve the computational efficiency. In this paper, we employ a logical disjunction that is equivalent to the cardinality constraint to develop valid inequalities. We first present general form of valid inequality implied by the disjunction. We next introduce some procedures that generate sequences of valid inequalities. Each generation procedure takes an existing valid inequality as input and returns another valid inequality when certain conditions are met. We also prove that the sequence of valid inequalities is finite. Then, we use the aforementioned disjunction to derive some valid inequalities known in the literature.

3 - Practical exact penalty and application to complexity analysis of penalty function methods

Shotaro Yagishita, The Institute of Statistical Mathematics, Tachikawa-shi, Japan, Masaru Ito

One of the typical approaches to constrained optimization problems is to use a penalty function. The theory of exact penalties allows the constrained minimization problem to be solved by a single unconstrained optimization problem. From a practical point of view, the implications of the existing theory are poor and not well connected to the theoretical analysis of the algorithm. We propose a practical theory of exact penalties. The theory allows for the analysis of the iterative complexity of penalty function methods of finding an approximate stationary point that satisfies the constraint.

4 - Beyond Traditional Robustness: Relaxing Connectivity for Robust Graph Partitions

Raunak Sengupta, University of Illinois, Urbana Champaign, Urbana, IL, United States, Rakesh Nagi, Ramavarapu S. Sreenivas

We address the challenge of generating robust solutions for the Balanced Connected k-Partition problem, where a connected graph is partitioned into k connected sub-graphs with equal node weights. This problem, arising in contexts like Area Coverage, Autonomous Construction, and Fair Allocation of Land, is known to be NP-Hard. We present provably good approximation algorithms that handle uncertainties in node weights. Although various robustness concepts exist in the literature, we demonstrate through pathological examples that these criteria can lead to undesirable solutions even when solved optimally. We establish two key structural results: 1) Robust solutions in practical settings require relaxing the connectivity constraint, and 2) A solution balancing loads and uncertainties simultaneously is highly robust and meets multiple robustness criteria within an acceptable approximation factor. Thus, finding a robust solution reduces to a two-dimensional load balancing problem on a graph with connectivity constraints, the two dimensions being node weight and uncertainty. For the case with 2 agents, we prove that a 1.5-approximation on both dimensions can be efficiently achieved and is the best possible guarantee. For the general case with m agents, we achieve a 2.66-approximation on both dimensions by relaxing connectivity constraints. Our approximation algorithms are supported by multiple interesting existential and structural results. Finally, an extensive numerical analysis is presented, where we demonstrate our algorithms' near-optimal performance and
ability to generate robust solutions.

Advancements in Sensor and Data Applications

Contributed Session

Chair: Ziwei Liu, The UNIVERSITY OF TENNESSEE, Knoxville, TN, United States

1 - Electromyography signal synthesis for privacy protections using a generative adversarial network

Liwei Qing, North Carolina State University, Raleigh, NC, United States, Bingyi Su, Lu Lu, Sehee Jung, Xu Xu

Electromyography (EMG) signal analysis is essential for understanding muscle activity and fatigue, providing valuable insights into the prevention of work-related musculoskeletal disorders (WMSDs). However, the availability of open-access EMG databases is very limited because these data are collected from human subjects, raising privacy concerns regarding their sharing. To overcome this limitation, this study employs a generative adversarial network (GAN) to synthesize non-identified EMG signals for manual material handling (MMH) tasks, enhancing data availability for workplace safety and health studies while maintaining privacy. We analyze DoppelGANger, a prominent GAN variant for time series data and metadata generation, evaluating its efficiency and efficacy. The EMG dataset used for training and testing was sourced from our previous MMH experiment. To evaluate our synthetically generated dataset, we compare the statistical features of the real and synthetic datasets. The mean of the real data is 1.045×10^{-2} mv with a standard deviation of 1.553×10^{-2} mv , while the mean of the synthesized data is 1.084×10^{-2} mv with a standard deviation of 1.57×10^{-2} mv . The Wasserstein distance between the two datasets is 0.1755. These results demonstrate the effectiveness of using GAN models in generating high-fidelity EMG signals for MMH tasks, addressing the data shortage in occupational health research. Future research should incorporate more MMH task data and generate EMG signals conditioned on the input task type.

2 - Medical Machine Learning Model for Predicting 6-Min-Walk-Test Results

Sa Eun Park, Major in Industrial Data Science & Engineering, Department of Industrial Engineering, Pusan National University, Busan, Korea, Republic of, Ki Hun Kim, Myung Jun Shin, Tae Sung Park, Sang Hun Kim

The 6-minute walk test (6MWT) measures the walking distance of a subject during 6 minutes to evaluate the subject's exercise tolerance and functional aerobic capacity. It is the most established functional exercise capacity test among respiratory rehabilitation tests. The 6MWT results can be utilized to classify the subjects into one of normal gait capacity group (stable group) and low gait capacity group (risky group).

However, 6MWT requires not only the space for subjects to walk but also its examiners, which makes considerable costs. These costs will be significantly saved if only the persons expected to get risky results from 6MWT are pre-screened and then conducted for 6MWT. To realize the cost saving, this study develops a medical machine learning model for predicting the 6MWT results from the prior test results of 6MWT such as body composition test and physical function test. The model was designed to satisfy two essential requirements for its applicability to hospitals. Firstly, the inputs of the model were defined to be collectable from hospitals. Secondly, the model was interpreted to be understandable for clinicians to accept and utilize it. Specifically, this study identified key predictors of the model with Shapley values and derived an easily understandable function from the model via symbolic meta-modeling. The satisfaction of these two requirements makes the developed model operate well in real contexts of hospitals, which contributes to the establishment of pre-screening for 6MWT and enhance its cost efficiency.

3 - A Decision Support Framework for Building Energy Efficiency and Productivity Based on a Sensor Network

Ziwei Liu, University of Tennessee, Knoxville, Knoxville, TN, United States, Mingzhou Jin

This research focuses on optimizing energy consumption and improving occupant health and productivity in office buildings through the integration of a sensor network. Initially, a detailed building geometry model, inclusive of the HVAC system, is developed using OpenStudio. Subsequently, a sensor network is employed to gather real-world performance data from the building. This data is crucial for calibrating the developed model, ensuring that the simulations accurately reflect the building's actual energy consumption and performance characteristics. The study then conducts a series of experiments aimed at enhancing Indoor Air Quality (IAQ) and, by extension, occupant well-being and productivity. These experiments involve fine-tuning various parameters, including indoor air intake and occupant density, to find their impact on the indoor environment. Finally, the research seeks to find an equilibrium between minimizing energy usage and maximizing occupant health and productivity. This is achieved through the optimization of the HVAC system, focusing on temperature and lighting setpoints, air filtration, and fan power levels, alongside refining occupancy schedules. Overall, this study provides actionable insights and practical strategies in enhancing building efficiency while simultaneously ensuring occupant health and productivity are maintained at optimal levels.

1 - Artificial Intelligence in Cybersecurity: A New Paradigm Revolutionising Threat Intelligence and Defense Mechanism

Utkarsh Sinha, California State University, Long Beach, Long Beach, CA, United States, Laasya Priya Muktevi

The increasing sophistication and frequency of cyber-attacks necessitate a shift from traditional, reactive cybersecurity measures to more proactive and advanced defense mechanisms. This paper discusses the integration of Artificial Intelligence (AI) with Cyber Threat Intelligence (CTI), emphasising its transformative impact on cybersecurity. By automating the CTI cycle from requirement gathering to feedback. AI enhances the ability to detect cyber intrusions swiftly, automate threat responses, and refine defense strategies against emerging threats. We explore various AI techniques such as machine learning, deep learning, and natural language processing, which facilitate the identification of malicious patterns and activities with unprecedented speed and accuracy. Moreover, the paper highlights the need for secure implementation of AI technologies to prevent adversaries from exploiting AI-powered systems. Overall, the integration of AI with CTI represents a significant shift towards proactive cybersecurity, enabling organizations to not only anticipate but effectively counteract potential cyber threats.

2 - The Impact of AI on the Product to Market feedback loop in the technology industry.

Jiaqi Chen, Google, Chicago, IL, United States, Devika Naik, Nagesh Gulkotwar, Khyathi Balusu

The technology industry's swift evolution has seen AI become a transformative force in various aspects of product development and market analysis. This paper explores the transformative effects of AI on the product-to-market feedback loop, critical for market responsiveness and customer-centric product development.

Traditional product-to-market loops enable rapid product changes based on market insights, ensuring products are customer-focused. However, the process is hampered by time-consuming data collection, scalability issues, and potentially biased insights. These challenges hinder companies' ability to adapt to market shifts. AI can address these challenges by automating data analysis, enhancing scalability, minimizing bias and informing decision-making.

The paper utilizes a qualitative research approach, conducting online interviews with 20 participants across multiple process oriented roles in the US technology sector (e.g., product managers, analysts, customer success managers etc.). The literature review explores current AI methodologies which includes but is not limited to Generative AI, Natural Language Processing and Sentiment Analysis to offer research context. Data collection was conducted through Google Forms, facilitating the identification of trends related to the study's objectives.

Findings reveal that AI can enhance several stages of the feedback loop, including feedback capture, data retrieval, ticket management, data analysis, and generating recommendations. These AI-powered refinements streamline processes, improve accuracy, and enable faster responses to market shifts.

This research concludes that AI is set to transform the product-to-market loop in the technology sector. By empowering companies to innovate rapidly, anticipate customer needs, and thrive in a competitive landscape, AI is poised to redefine product development.

3 - Balancing Growth and Opportunity: AI's Role in Shaping Freelancers' Skills and Market Behavior

Eunah Cho, Baruch College, City University of New York, New York, NY, United States, Qiang Gao

Artificial intelligence (AI) has profoundly reshaped the freelance sector. This study investigates the intricate interplay between exploration and exploitation dynamics within the freelance realm in the context of ChatGPT adoption. Based on theories of exploitation and exploration, we first hypothesize how workers respond to the emerging ChatGPT in terms of skill development and how their responses affect their contracting and future performance. Using a comprehensive dataset from one of the largest online freelancer platforms, we employ a Difference-in-Differences approach to assess the impact of AI adoption. The study reveals a shift towards exploring skills among freelancers using ChatGPT, suggesting an adaptation to the automation of more routine tasks by AI. Concurrently, freelancers are experiencing an increased competitive advantage in bidding, as those effectively utilizing ChatGPT are enhancing their proposals or optimizing their bidding strategies to win more specialized tasks that align with their newly acquired skills. Despite these changes, work quality ratings have remained stable, indicating that the acquisition of new skills and an increase in winning bids have not compromised the quality of work delivered. However, a decline in time consumed to complete projects implies that freelancers can potentially boost their competitiveness in a market, showcasing their successful adaptation to technological advancements. This study contributes to our understanding of how AI technologies, exemplified by ChatGPT, are shaping the future of work in the freelance domain. This research also offers valuable insights for freelancers, platforms, policymakers, and other stakeholders navigating the evolving landscape of digital labor.

4 - Accelerating the Development of Digital Twins using Generative AI

Khaled Salah, Khalifa University, Abu Dhabi, United Arab Emirates, Senay Gebreab, Raja Jayaraman

Digital twins (DTWs), virtual representations mirroring physical assets, processes, or systems, have emerged as pivotal tools across many industries, aiding in predictive maintenance, optimization, and decision-making. However, their development often requires significant challenges, including data scarcity, model complexity, and computational demands. Generative AI (or GenAI) is a subset of AI techniques that focus on creating new data or content in the form of audio, video, images, or text. In this presentation, we demonstrate with examples and use cases how GenAI can accelerate the creation and development of DTWs. Specifically, we first show how GenAI can accelerate the generation of 3D models for DTWs by using 3D diffusion models to generate 3D assets from a single or few 2D images of an object. Second, we demonstrate how Large Language Model (LLM)-based assistants can automate the integration of data sources with a DTW and help establish communication between physical devices and the DTW model. Third, we illustrate how GenAI can facilitate code generation to streamline the development of data pipelines in DTWs by generating code for API integration, data processing, and storage. Fourth, we show how GenAI can enable interactive and dynamic visualization of DTW data and events based solely on natural language user input. Fifth, we test how generated data and synthetic scenarios can help in predictive simulation. Lastly, we highlight the use of GenAI in drawing actionable insights from collected past data to support decision-making processes.

5 - AI and Leadership

Farzaneh Moghadam, UNT, Denton, TX, United States

In industries across the globe, the integration of Artificial Intelligence (AI) is transforming leadership and management fundamentally. In this review, we explore the changing role of leaders in an AI-enhanced environment, highlighting the need for new competencies and ethical considerations. With AI technologies like machine learning and predictive analytics, decision-making is moving away from hierarchical models and toward data-driven frameworks, fostering a collaborative and innovative culture. Despite these challenges, however, transparent and accountable leadership is necessary to address algorithmic bias and privacy concerns. In today's workplace, AI is compulsory for employees, but what about leaders, CEOs, and managers?

This review synthesizes key findings from key studies, emphasizing the dual role AI can play in empowering organizations as well as replacing human leadership. Despite AI's benefits in strategic decision-making and operational efficiency, its limitations in replicating human emotional intelligence and ethical judgment underscore the need for human oversight.

Methodologically, our study collects comprehensive data on the intersection of AI and leadership by interviewing AI experts, business leaders, and HR professionals. An analysis of these interviews provides insight into organizational transformation, ethical challenges, and skills development. Leaders need to develop strategies that align AI capabilities with organizational goals, foster interdisciplinary collaboration, and embrace continuous learning.

In conclusion, navigating the AI-driven landscape demands a strategic vision, inclusive culture, and ethical accountability. Leaders who can effectively integrate AI into their decision-making processes while maintaining transparency and fostering innovation will be well-positioned to drive sustainable growth and maintain stakeholder trust in the AI era.

6 - Autonomous Agents and Monetary Policy: Can the Fed Run on Autopilot?

Emily Struble, University of Miami, Miami Herbert Business School, Coral Gables, FL, United States, Erotokritos Skordilis, Stefanos Delikouras

This work assesses the application of artificial intelligence (AI) on monetary policy. The goal of monetary policy, conducted by the Federal Reserve, is maximum employment, stable prices, and moderate long-term interest rates. One of the most important tools in monetary policy is the Fed interest rate, which is charged to banks on loans they receive from the Fed. The Fed rate is important because it can stimulate or contract the economy. For instance, during Covid and the 2007 economic crisis, the Fed rate was set to zero to foster economic growth. To the contrary, after Covid, the rate was increased to suppress inflation.

Reinforcement learning is a machine learning method that has recently gained traction in financial applications. Unlike other types of machine learning, reinforcement learning is a goal-directed method where the model (agent), through a continuous trial-and-error approach, learns to navigate its surrounding environment to maximize a cumulative long-term reward.

The scope of this work is to evaluate monetary policy decisions, namely the level of the Fed rate, suggested by scalable reinforcement learning agents, and compare them to the actual human-induced policies. This allows for performance assessment of machine learning in conducting monetary policy.

Equity and Fairness in Online Decision Making

Invited Session

Auctions and Market Design

Chair: Will Ma, Columbia Business School, New York, United States

Co-Chair: Eric Balkanski, Columbia University, New York, NY, United States

Co-Chair: Andreas Maggiori, Columbia University, New York, NY, 10027, United States

1 - Fair Algorithms with Unfair Predictions

Andreas Maggiori, Columbia University, New York, NY, United States, Eric Balkanski, Will Ma

Algorithms with predictions, also called learning-augmented algorithms, is a recent framework for decision-making that leverages the power of machine-learned predictions without making any assumption about their quality. The goal is to improve the algorithm's performance when predictions are accurate while maintaining acceptable guarantees when predictions are erroneous. Due to challenges with fairness in machine learning, a serious concern is that learning-augmented algorithms could leverage biased predictions and, as a result, make unfair decisions. We study the classical secretary problem in the learning-augmented setting, and prove that such a concern is indeed legitimate. Current learning-augmented algorithms for that problem are initially given predictions about the candidates' values and select a candidate that is guaranteed to have value that is a $\max \{ \Theta (1) , 1 - O(\epsilon) \}$ approximation to the maximum value, where ϵ is the approximation error. However, these algorithms may pick the best candidate with vanishing probability. Our main result is a novel algorithm that achieves a $\max \{ \Theta (1) , 1 - O(\epsilon) \}$ approximation while also guaranteeing that the best candidate is selected with constant probability. We also extend our result to the k-secretary problem.

2 - Bridging Theory and Practice for Balancing Notions of Equity with Small Portfolios

Jai Moondra, Georgia Institute of Technology, Atlanta, GA, United States, Swati Gupta, Mohit Singh

In this work, we present a novel approach to address the challenge of choosing the right notion of fairness in various optimization problems. We introduce the concept of "portfolios" -- a set of solutions that contains an approximately optimal solution for each objective in a given class of objectives, such as Lp norms. This concept opens up new possibilities for getting around the “right” notion of fairness for many problems by summarizing the space of "good enough representative" solutions. We exemplify our approach for the fair facility location and scheduling problems. The former tries to balance access costs to open facilities that are borne by different groups of people, and the latter the load on machines. This can be done by minimizing an Lp norm or an ordered norm, however, there is no clear choice of “p” in the current literature, or the weights for an ordered norm. We demonstrate construction of small portfolios for these problems, and the trade-offs with the achievable approximation and the size of the portfolio. Further, motivated by the Justice40 Initiative that provides rolling budget investments, we impose a refinement-like structure on the portfolio for facilities opened over time. We develop novel approximation algorithms for these structured portfolios and show experimental evidence of their performance in US counties. We also present a planning tool that provides potential ways to expand access to U.S. healthcare facilities, which might be of independent interest to policymakers.

3 - Redesigning Service Level Agreements: Equity and Efficiency in City Government Operations

Zhi Liu, Cornell Tech, New York, NY, United States, Nikhil Garg

We consider government service allocation -- how the government allocates resources (e.g., maintenance of public infrastructure) over time. It is important to make these decisions efficiently and equitably -- though these desiderata may conflict. In particular, we consider the design of Service Level Agreements (SLA) in city government operations: promises that incidents such as potholes and fallen trees will be responded to within a certain time. We model the problem of designing a set of SLAs as an optimization problem with different equity and efficiency objectives under a queuing network framework; the city has two decision levers: how to allocate response budgets to different neighborhoods, and how to schedule responses to individual incidents. We: (1) Theoretically analyze a stylized model and find that the ``price of equity'' is small in realistic settings; (2) Develop a simulation-optimization framework to optimize policies in practice; (3) Apply our framework empirically using data from NYC, finding that: (a) status quo inspections are highly inefficient and inequitable compared to optimal ones, and (b) in practice, the equity-efficiency tradeoff is not substantial: generally, inefficient policies are inequitable, and vice versa.

4 -

Fair Ranking in the Cascade Model

Ozge Sahin, Johns Hopkins Carey Business School, Baltimore, MD, United States, Wentao Lu, Ruxian Wang

In the cascade model, the optimal solution is to rank sellers in decreasing order of revenues, which raises the concern of fairness as sellers with low-ranking positions receive little consumer attention. To alleviate this unfairness, we consider imposing different fairness constraints for the platform. We find that the problem after imposing minimum purchase probabilities on all sellers can be solved in polynomial time by solving the separation problem of the dual problem, which is equivalent to solving an optimal ranking for a cascade model with shifted revenues. We then consider the fairness constraints of imposing lower bounds of probability for each product to be placed in the top k positions. We identify conditions for the problem to be feasible. For the case of $k=1$, we show that the optimal solution is to offer n different rankings. For general case, we propose a simple heuristic with $1/2$ performance guarantee and a polynomial approximation scheme.

5 - Recurring Magician's Problem and Applications to Bayesian Task Assignment

Mohammad Reza Aminian, The University of Chicago, Booth School of Business, Chicago, IL, United States, Rad Niazadeh

Motivated by applications in online education platforms for curating and assigning tutoring sessions to teachers, we study a generalization of the online contention resolution scheme problem for uniform matroids—also known as the Magician's problem introduced in Alaei (2014). In this generalization, the decision maker sequentially interacts with elements that leave after each interaction and return at some point in the future. Once an element returns, the decision maker observes whether it is active or not and, if active, decides whether to select this element given a capacity constraint. Each time a selected active element returns, it also replenishes the capacity by one unit. The goal is to design an online algorithm that maximizes the probability that any element is selected each time the element returns, conditioned on the arriving element being active. We introduce a novel family of online algorithms that as an invariant induce a stationary distribution over the states. By studying this induced stationary distribution, we show that there exist simple polynomial-time online algorithms that obtain a minimum probability of $1 - \Theta(1/\sqrt{k})$ to select active elements each time they return or arrive for the first time, where k is the amount of capacity. As a corollary of our result, we also obtain a novel, yet simple and interpretable, asymptotically optimal online algorithm for the standard Magician problem in Alaei (2014), which might be of independent interest.

Advanced Reinforcement Learning and Optimization Techniques

Contributed Session

Chair: Yilie Huang, Columbia University, New York, NY, United States

1 - Accelerating Low-Rank Factorization-Based Semidefinite Programming Algorithms on GPU

Qiushi Han, University of Illinois Urbana-Champaign, Urbana, IL, United States, Zhenwei Lin, Hanwen Liu, Caihua Chen, Deng Qi, Dongdong Ge, Yinyu Ye

In this paper, we address a long-standing challenge: how to achieve both efficiency and scalability in solving semidefinite programming problems. We propose breakthrough acceleration techniques for a wide range of low-rank factorization-based first-order methods using GPUs, making the computation much more efficient and scalable. To illustrate the idea and effectiveness of our approach, we use the low-rank factorization-based SDP solver, LoRADS, as an example, which involves both the classic Burer-Monterio method and a novel splitting scheme with a starting logarithmic rank. Our numerical results demonstrate that the accelerated GPU version of LoRADS, cuLoRADS, can solve huge-scale semidefinite programming problems with remarkable efficiency. By effectively leveraging GPU computational power, cuLoRADS exhibits outstanding performance. Specifically, it can solve a set of MaxCut problems with 10^7 ×10^7 matrix variables in 10 seconds to 1 minute each on an NVIDIA H100 GPU with 80GB memory, whereas previous solvers demonstrated the capability of handling problems of this scale, required at least dozens of hours per problem on CPUs. Additionally, cuLoRADS shows exceptional scalability by solving 1) a MaxCut problem with a 170 million × 170 million matrix variable and 2) a Matrix Completion problem with a 20 million × 20 million matrix variable and approximately 200 million constraints, both in a matter of minutes.

2 - Simulation-Based Optimistic Policy Iteration In Identical-Interest Markov Games with KL Control Cost

Khaled Nakhleh, Texas A&M University, College Station, TX, United States, Ceyhun Eksin, Sabit Ekin

This work proposes an agent-based optimistic policy iteration (OPI) scheme for learning stationary optimal stochastic policies in identical interest Markov games, in which agents incur a Kullback-Leibler (KL) divergence cost for their control efforts.
This extends the KL optimal control framework for Markov decision process (MDPs) to multi-agent Markov games, which we call KL control identical-interest multi-agent games.
We introduce the Kullback-Leibler control optimistic policy iteration KLC-OPI scheme for learning an agent-based optimal policy.
KLC-OPI consists of a greedy policy improvement step, that is shown to follow a Boltzmann distribution, followed by an m-step temporal difference (TD) policy evaluation step.
KLC-OPI is shown to converge to the optimal stochastic policy asymptotically in the case of evaluating the entire state space (synchronous update), and when a subset of the state space is evaluated (asynchronous update) in each scheme iteration.

Based on the asynchronous m-step TD policy evaluation step of the scheme, we design an asynchronous, model-based, tabular multi-agent reinforcement learning algorithm, OPTIMAL: OPTimistic Policy Iteration for Multi-Agent Learning.
OPTIMAL evaluates the current policy using noisy m-step TD trajectories and updates the agents' value functions based on the unbiased noisy return.
Simulation results on a KL control variant of the Stag-Hare game validates our learning algorithm's performance in terms of minimizing the cost return.

3 - A Stability Principle for Learning under Non-Stationarity

Chengpiao Huang, Columbia University, New York, NY, United States, Kaizheng Wang

We develop a versatile framework for statistical learning in non-stationary environments. In each time period, our approach applies a stability principle to select a look-back window that maximizes the utilization of historical data while keeping the cumulative bias within an acceptable range relative to the stochastic error. Our theory showcases the adaptability of this approach to unknown non-stationarity. The regret bound is minimax optimal up to logarithmic factors when the population losses are strongly convex, or Lipschitz only. At the heart of our analysis lie two novel components: a measure of similarity between functions and a segmentation technique for dividing the non-stationary data sequence into quasi-stationary pieces.

4 - Sublinear Regret Bounds for An Actor-Critic Algorithm in Continuous-Time Linear-Quadratic Reinforcement Learning

Yilie Huang, Columbia University, New York, NY, United States, Yanwei Jia, Xunyu Zhou

We study reinforcement learning (RL) for continuous-time linear-quadratic (LQ) control where the volatility of the state process is both state- and control-dependent. We develop a model-free approach that relies neither on the knowledge of model parameters nor on their estimations, and devise an actor-critic algorithm to learn the optimal policy parameter. Our main contributions include the introduction of a novel exploration scheduling scheme, as well as a regret analysis of the proposed algorithm. We provide the convergence rate of the policy parameter to the optimal one, and prove that the algorithm achieves a regret bound of $O(N^{\frac{3}{4}})$. We conduct a simulation study to validate the theoretical results and demonstrate the effectiveness and reliability of the proposed algorithm. We additionally perform numerical comparisons of our algorithm against recent studies on model-based stochastic LQ RL algorithms adapted for state- and control-dependent volatility settings, demonstrating superior performance of our approach in terms of regret bounds.

Data-driven Decisions: Insights and Impact Across Industries

Contributed Session

Chair: Yuan Qu, University of Hong Kong, Hong Kong, N/A, Hong Kong

1 - Analysis of the Impact of Fabricated Consumer Data on Corporate Profitability

bingchan Yang, Beijing Institute of Technology, Beijing, China, People's Republic of, Meichen Liu

Analysis of the Impact of Fabricated Consumer Data on Corporate Profitability

Abstact

This study aims to delve deeply into the multidimensional impact mechanism of consumer information falsification on corporate revenue. In the context of the information society, consumer data, as a critical resource, plays a vital role in determining the efficiency of information utilization and corporate revenue. However, consumers often provide false information due to privacy concerns, potentially leading to economic losses for enterprises. By constructing a theoretical model, this study systematically explores the relationship between privacy protection investment and the proportion of falsified consumer information, and further reveals how this relationship affects corporate revenue. The findings indicate that effective privacy protection investment can significantly reduce the proportion of false information, thereby enhancing the economic benefits of enterprises. Additionally, this study analyzes the specific impacts of various parameters, such as platform basic utility and the loss coefficient of information utilization, on corporate revenue, providing profound academic insights and practical guidance for enterprises in developing privacy protection and information management strategies.

KeyWord: Privacy Safeguarding /Corporate Earnings/ Information Misrepresentation

2 - Redesigning Medicare Shared Savings Program: Implications for Risk-Averse ACOs

Dawei Jian, University of Wisconsin - Milwaukee, Milwaukee, WI, United States

The Medicare Shared Savings Program (MSSP) is designed to curb rising Medicare costs by incentivizing Accountable Care Organizations (ACOs) to provide healthcare more efficiently. However, faced with the obligation to assume financial risk, nearly two-thirds of ACOs withdrew from the MSSP. How should Medicare redesign MSSP to incentivize spending saving and encourage participation? We formulate the long-term MSSP through a dynamic principal-agent model, in which the Medicare provides a performance-based subsidy to partially reimburse ACOs' investments, considering their risk-aversion and the stochastic evolution of their private spending-saving abilities. Unlike the current cap-based system, we recommend lowering benchmarks and sharing rates initially, adjusting them over time based on the persistence of ACOs' abilities. Utilizing a dataset from CMS, we analyzed ACOs' risk attitudes to demonstrate how our approach could outperform the existing one.

3 - *Role of Individual differences in cybersecurity decision making in a workplace*

Sahar Farshadkhah, University of Illinois Springfield, Springfield, IL, United States

For several years, Ponemon Institute Data Breach Report showed that insiders are the weakest link in the cybersecurity management chain. Organizations increase their investment in cybersecurity drastically but still cybersecurity attacks costs significant amounts every year. It has never been more vital to do research on human-centric interventions. This study aims to explore the role of individual differences in explaining cybersecurity behaviors in the workplace. One of the main individual differences among employees could be their personality and how that affects their decision making while facing dilemmas related to complying with cybersecurity policies in a workplace. This study will look at this concept from a new angle and look for how individual differences and especially personality may change the known relationships among cybersecurity literature constructs. The findings has theoretical implications by extending the current literature and have practical implications for managers by helping them to have a better understanding of the role of individual differences in security-related behaviors and decision-making.

4 - Styling Box Selling to Strategic Buyers

Yuan Qu, University of Hong Kong, Hong Kong, Hong Kong, Max Z.J. Shen

Styling box selling is a new online shopping format rising recently. Instead of letting customers actively poodle around among numerous products on the platform, the styling box platform runs a passive shopping mode in which a customer will periodically receive a box of selected items. The customer can keep what they want and pay for them, then return everything else, where a discount will be applied if all the items are kept.

To explain the mechanism behind styling box selling, we take a holistic approach encompassing both a seller intent on maximizing profit and strategic buyers with heterogeneous preferences. First, we found that the rank of recommended items in the box, recommendation ordering, will significantly affect the profit structure. Under the homogeneous product setting, dominant recommendation ordering and discount strategies can be derived. Some monotonic dominance can also be ensured under the heterogeneous assumption. Then, we discuss a more general and realistic model with heterogeneous products and limited inventory, where the problem can be formulated as a Stackelberg knapsack game, an NP-hard bilevel integer programming. Besides recommendation ordering, we find that the structure of price ordering, the rank of price within all products, and valuation ordering, the rank of valuation to a product within all customers, provide unique properties in solving the problem.

Human-Centric Decision-Making: From Psychosis to Sports Data

Contributed Session

Chair: Jinwook Lee, Drexel University

1 - Brain Speaks Louder Than Words

Qi Zhao, Penn State University, University Park, PA, United States, Elena Karahanna, D.J. Wu, Min Ding

Surveying participants is common for researchers and practitioners alike to capture perceptions, attitudes, and opinions. The validity of collected responses matters as they shape further managerial insights and theoretical findings. To avoid biases inherent in self-reports, this research leverages neuroscientific measurement and devises a novel approach to infer participants' true opinions directly from cognitive processing. The proposed approach draws upon cognitive dissonance theory that suggests that individuals engage in systematic cognitive processing when presented with an opinion that is incongruent with their own views. Leveraging this, we sequentially present artificial stimuli to participants and observe their cognitive processing through neuroscientific measurement. More systematic cognitive processing should occur when the artificial stimulus is incongruent with the participant's true opinion. For validation, we conduct a lab study to collect and infer participants' food preferences. We find significant neural evidence revealing more systematic processing upon incongruent stimuli exposure. We also examine how object familiarity and presence of a heuristic cue moderate the accuracy of our method. Additionally, we provide robustness evidence demonstrating the persistency of the induced neural response through multiple exposure repetitions. Contrary to existing methods, the proposed approach entails no training data at the individual level to make inferences and no direct reporting from participants, making itself also appealing to studies requiring a continuous participation experience.

2 - Smart Decision for a Better World

Anwer Ayyub, GTS, Dubai, United Arab Emirates

The decision-making process involves understanding the situation's reality, engaging stakeholders, and coordinating with various parties to identify potential issues, ensure the right project is chosen, and effectively communicated.

Appreciation and ideation are interconnected in decision-making, requiring diverse perspectives to effectively address internal and external stakeholders.

The data emphasizes the significance of considering external and internal evidence based, such as staff disengagement and a performance target culture and KPI, in business functions. It highlights the need for deliberate contemplation, understanding personality issues, and conflict resolution, as well as a big picture perspective for effective communication.

The phrase "co-creating" or "co-appreciating" emphasizes the importance of understanding a situation by putting oneself in the picture and allowing others to react, fostering collective understanding.

The PRISM framework emphasizes the importance of understanding a situation and problem, distinguishing between them, and breaking down actions into short-term and long-term ones. It helps businesses understand their profit-driven culture and focus on value creation. A successful business transformation project, canceled due to conflict, was achieved through a adoption of this framework.

3 - A Reinforcement Learning-based Automated Negotiation Model for Sellers in the Supply Chain

Ga Hyun Lee, Kyung Hee University, Yongin-si, Korea, Republic of, Hyun Woo Jeon

The negotiation is a dynamic decision-making process with a lot of complex information to consider. Human negotiators, however, can have difficulties in making the optimal decision due to various limitations related to time, cost, and information processing capabilities. In addition, in the process of negotiation in the supply chain, sellers have to deal with bargaining power asymmetry, because they are typically small and medium-sized enterprises (SMEs). To address these issues, this study proposes an automated negotiation model from the perspective of sellers. In particular, we develop a reinforcement learning (RL) based model utilizing the Q-learning algorithm as RL technology is widely utilized to develop automated negotiation models. In addition, to deal with the insufficient amount of data, we simulate the multiple negotiation episodes based on the correlation structures of real transaction data; quantity (Q), price (P), and delivery lead time (D). Specifically, we generate more than 20,000 episodes for two negotiation cases: (i) negotiating P dependent on Q and (ii) negotiating P dependent on D. Then we suggest the model training results of each negotiation case. The results show that the developed model in this study can be applied to various negotiation situations and helpful for sellers in the supply chain.

4 - Decoding Decision-Making Processes: Bottom-Up Tree Construction through Model-Based Methods with Consideration of Data-Driven Approaches

Jinwook Lee, Drexel University, Philadelphia, PA, United States, LANQING DU, Sung-Cheol Kim, Matthew Schneider

Human decision-making inherently involves subjectivity. People often exhibit tendencies to favor those within their social circles, leading to differing treatment of individuals. Determining privilege, representation, and other relevant factors is a complex task. This research seeks to develop models for conducting comparative analyses with reduced subjectivity. We employ two main methodologies: model-based and data-driven approaches. In the model-based approach, we utilize set-theoretic operations to examine differences and similarities among groups, ensuring comprehensive coverage through subgroup division. Meanwhile, the data-driven approach involves calculating the importance of features using SHAP values to identify significant variables for each group. To validate these methods, we conduct extensive numerical experiments using a recent dataset comprising 51 judicial circuits and over 100,000 criminal justice outcomes from the Department of Community Supervision (DCS) in the State of Georgia.

Supply Chain Risk and Resilience

Contributed Session

Chair: Qiang Qiang, Penn State, Malvern, PA, United States

1 - Synergy or competition: how does the working capital of supply chain network members affect the performance of enterprises?

Mengyin Li, China Conservatory of Music, Beijing, China, People's Republic of, Hua Song, Xinge Ding

The operation of enterprise is influenced by its supply chain network. How does supply chain network working capital management affect firm performance? On the one hand, companies can benefit from shifting inventory and accounts pressures to upstream and downstream; on the other hand, improving the efficiency of the entire supply chain network can also bring benefits to enterprises. This study verifies the impact of inter-organizational capital efficiency on firm performance. This paper takes 214 listed manufacturing companies that disclose upstream and downstream information of their supply chains as research samples, and collects 1070 observations, as well as information from 13638 suppliers and 8562 customers, to conduct empirical research on supply chain network and working capital management. Research shows that companies benefit more when the average cash conversion cycle of all participating partners across the supply chain network is reduced.The synergy effect among supply chain networks is more significant than the competition effect.

2 - Dual-sourcing of capacity: Frequent batching or more on-demand?

Partha Mishra, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Sunil Chopra, Sebastien Martin, Karen Smilowitz

Dual-sourcing, a strategy that diversifies supply sources to manage uncertainty, is widely used in supply chain management. We extend this concept to the contexts of transportation and manufacturing, introducing the notion of "dual-sourcing of capacity." In these contexts, we model the trade-off between cost and responsiveness using two capacity sources: a cheaper batched source operating at a fixed frequency (e.g., shuttles or furnaces) and a more expensive on-demand source with unit capacity (e.g., Ubers or heat lamps). Unlike traditional dual-sourcing, which focuses on the supply of goods, we use the term sourcing to mean using a resource's capacity to perform a task, e.g., using vehicles to transport passengers or using heating equipment to process semiconductor wafers. We prove that a simple threshold policy, which we call "Q-policy", is optimal under certain restrictions. Lowering the threshold Q in Q-policies increases on-demand use in our setting; however, we find it is never optimal to reduce Q below the batched source's batch size. Furthermore, when the optimal Q is unchanged, greater responsiveness is achieved by increasing the frequency of using the batched source, which reduces the on-demand usage, challenging conventional wisdom. Our findings from the fresh perspective of dual-sourcing provide useful insights for managing uncertainty in transportation and manufacturing contexts.

3 - The Multi-period Interactive CLSC Network

Qiang Qiang, Penn State, Malvern, PA, United States

Inspired by the recent business cases, we develop a coupled multi-period CLSC network model dealing with heterogeneous products facing different demand markets. The end-of-life product from the forward supply chain is collected, recycled and the raw material is extracted to be used as an input for the reverse supply chain which produces another type of product. In particular, interactions between the two supply chains with inventory cost and innovation competition are analyzed. An algorithm is introduced to study the network equilibrium. Numerical examples are used to illustrate the model.

1 - A tail-risk sensitive reinforcement learning approach for option hedging

Xianhua Peng, Peking University, Shenzhen, China, People's Republic of, Xiang Zhou, Bo Xiao, Yi Wu

We propose a new risk-sensitive reinforcement learning approach for the dynamic hedging of options and other derivatives. The approach focuses on the minimization of the tail risk of the final P&L of the seller of options. Different from most existing reinforcement learning approaches that require a parametric model of the underlying asset, our approach can learn the optimal hedging strategy directly from the historical market data without specifying a parametric model. Our approach presents an efficient way to incorporate the tail risk measures of the final P&L into traditional reinforcement learning framework in a model-free setting. We carry out comprehensive empirical study to show that, in the out-of-sample tests, the proposed reinforcement learning hedging strategy can obtain statistically significantly lower tail risk and higher mean of the final P&L than traditional delta hedging methods.

2 - Systemic Values-at-risk: Computation and Convergence

Cagin Ararat, Bilkent University, Ankara, Turkey, Mustafa Çolak

We investigate the convergence properties of sample-average approximations (SAA) for set-valued systemic risk measures. We assume that the systemic risk measure is defined using a general aggregation function with some continuity properties and value-at-risk applied as a monetary risk measure. Our focus is on the theoretical convergence of its SAA under Wijsman and Hausdorff topologies for closed sets. After building the general theory, we provide an in-depth study of an important special case where the aggregation function is defined based on the Eisenberg-Noe network model. In this case, we provide mixed-integer programming formulations for calculating the SAA sets via their weighted-sum and norm-minimizing scalarizations. To demonstrate the applicability of our findings, we conduct a comprehensive sensitivity analysis by generating a financial network based on the preferential attachment model and modeling the economic disruptions via a Pareto distribution.

3 - Index Investing and Dynamic Information Environment

Yiwen Shen, HKUST, Hong Kong, Hong Kong, Yueting Jiang

In this paper, we study how index investing and dynamic information environment affect market volatility, correlation, and price informativeness. We consider an overlapping generation model with multiple risky assets.The market has two classes of investors, with the first type trading single stocks and the second type trading an index fund. The single-stock investors have access to the private signal of the stock they trade, while the index investors rely on public information. The information environment varies in response to the investors' composition, capturing a feedback effect that more single-stock investors increase the amount of available information. We solve the investors' participation choice and optimal demands that clear the market under a framework of rational expectation equilibrium. Our model reveals the impact of indexing, information asymmetry, and stock correlation on the market equilibrium.

4 - Data-Driven Option Pricing

Xi Yang, National University of Singapore, Singapore, Singapore, Min Dai, Hanqing Jin

We propose an innovative data-driven option pricing methodology that relies exclusively on the dataset of historical underlying asset prices. While the dataset is rooted in the objective world, option prices are commonly expressed as discounted expectations of their terminal payoffs in a risk-neutral world. Bridging this gap motivates us to identify a pricing kernel process, transforming option pricing into estimating expectations in the objective world. We recover the pricing kernel by solving a utility maximization problem, and estimate the expectations in terms of a functional optimization problem. Leveraging the deep learning technique, we design data-driven algorithms to solve both optimization problems over the dataset. Numerical experiments are presented to demonstrate the efficiency of our methodology.

5 - Portfolio Selection with Time-Varying Taxation

Xianhao ZHU, The Chinese University of Hong Kong, Hong Kong, China, People's Republic of, Chen Yang

We present an optimal control framework for the continuous-time portfolio selection problem under time-varying capital gains taxes. Our study focuses on the investor’s decision in anticipation of tax rate adjustments. Our results suggest that, in contrast to a constant tax rate, investors tend to realize capital gains while deferring a significant proportion of capital losses in response to a tax rise. The magnitude of the tax rate increment determines the extent of capital gains realization. Conversely, investors refrain from realizing capital gains as the date of a tax cut approaches. We also examine scenarios where the direction of the tax rate is uncertain, as well as cases involving an intermediate period before the adjusted tax rate takes effect. Our results align with the empirical findings and contribute to the understanding of market behavior preceding a capital tax rate adjustment.

1 - Asymptotic Optimality of Dual Base-Stock Policies for Omni-Channel Perishable Inventory Systems

Yin Pan, Zhejiang University, Hangzhou, China, People's Republic of, Sentao Miao, Jinzhi Bu, Mingzheng Wang

We consider periodic review omni-channel inventory systems where there are an online channel and an offline channel selling the same perishable product with a fixed product lifetime over an infinite planning horizon. In online channel, it sells the product with a shorter lifetime and the outdated product goes to the offline channel. Unsatisfied demand can be either lost or backlogged. The objective is to minimize the long-run average holding, penalty, and outdating cost. The optimal policy for perishable system is notoriously complex and computationally intractable because of the curse of dimensionality. While there exist asymptotic results in the literature for single-channel perishable inventory systems, no paper has specifically focused on omni-channel perishable inventory systems. In this paper, we first focus on the omni-channel perishable system under a first-in-first-out issuance policy and show that a simple dual base-stock policy is asymptotically optimal when any one of the product lifetime, unit penalty cost, and unit outdating cost becomes large; moreover, its optimality gap converges to zero exponentially fast in the first parameter. We then derive the same theoretical results for the omni-channel perishable system under a last-in-first-out issuance policy. Finally, we provide a numerical study to demonstrate the performances of dual base-stock policies in these systems.

2 - Learning to Price Supply Chain Contracts against a Learning Retailer

, Xuejun Zhao, Ruihao Zhu, William Haskell

In this paper, we study the supply chain contract design problem faced by a data-driven supplier (she) who needs to respond to the inventory decisions of the downstream retailer (he). Both the supplier and the retailer are uncertain about the market demand and need to learn about it sequentially over a fixed time horizon. In addition, the supplier does not know the retailer's inventory learning policy, which may change dynamically. The goal for the supplier is to develop data-driven pricing policies with sublinear regret bounds under a wide range of possible retailer inventory learning policies. We establish a connection with nonstationary online learning by following the notion of a variation budget. We start by making the observation that existing approaches for non-stationary online learning cannot precisely delineate the dynamics incurred by the retailer's inventory learning policy. To overcome this challenge, we introduce a new notion of variation budget, which better quantifies the impact of the retailer's learning on the supplier's decision-making environment. We then proceed to propose dynamic pricing policies for the supplier for both discrete and continuous demand distributions, which lead to sublinear regret bounds for the supplier. Our pricing policies empirically outperform those from the existing non-stationary learning literature. At the managerial level, we answer affirmatively that there is a pricing policy with a sublinear regret bound for the supplier under a wide range of retailer inventory learning policies, even though she faces a learning retailer and an unknown demand distribution.

3 - Robust Optimal Selling Mechanism under Non-linear Utility

Yicheng Liu, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Pin Gao, Shixin Wang, zhen wang, Zizhuo Wang

We consider a robust mechanism design problem in which a seller wishes to choose a selling mechanism to maximize the revenue obtained from a buyer with private willingness-to-pay information and a nonlinear utility function. The objective is to provide a profit guarantee for the seller across all possible willingness-to-pay distributions whose mean and variance are consistent with the prior information. When the utility function is of a quadratic form and the coefficient of variation is low, we find that a quadratic pricing mechanism yields the optimal revenue guarantee. In this case, the worst-case distribution of willingness-to-pay follows a Pareto distribution. However, when the coefficient of variation is high, a unit price mechanism is optimal. We further extend our analysis to general elasticity utility functions and investigate how the optimal worst-case revenue varies with elasticity and coefficient of variation. Furthermore, given the widespread implementation of a two-part tariff mechanism in real-world scenarios, we also study the optimal two-part tariff mechanism. We show that under the quadratic utility form, the optimal two-part tariff pricing strategy achieves at least 80% of the optimal worst-case revenue when compared with the optimal robust mechanism. We also develop corresponding performance guarantees when the elasticity coefficient is less than two. However, when the elasticity coefficient exceeds two, the competitive ratio of the two-part pricing scheme goes to zero as the variance of willingness-to-pay grows to infinity.

4 - Peer Review Market Design

Craig Fernandes, University of Toronto, Toronto, ON, Canada, James Siderius, Raghav Singal

Peer review is a cornerstone of academic research, but its effectiveness depends on reviewers exerting costly effort to evaluate papers. This study addresses how peer review markets can be designed to incentivize high levels of reviewing effort and better identify paper quality. We analyze a one-sided market where each agent acts as both an author and a reviewer, with the central designer (e.g., conference organizer) aiming to maximize the number of high-quality submissions accepted by employing various matching mechanisms. We first show that the random matching mechanism (similar to current practice) can be arbitrarily bad as it always induces zero reviewing effort. Second, we study a recently proposed symmetric matching mechanism that pairs high-quality reviewers with other high-quality reviewers (and similarly for low-quality reviewers). While this approach is an improvement over random, it can be exploited by low-quality authors who prefer lower quality (and thus noisier) reviews, leading to bad market outcomes. To address these challenges, we propose a new admission control mechanism, which rejects papers from reviewers who fail to exert effort. Though stringent, this mechanism achieves the first-best welfare. We explore several extensions where effort levels are noisily observed and where authors upload preprints to disclose their reputation, finding consistent results across these variations. We conclude with practical insights for enhancing the effectiveness of peer review. To the best of our knowledge, we are the first to understand the value of operational levers such as matching and admission control in the design of peer review markets.

1 - Demand Balancing in Primal-Dual Optimization for Blind Network Revenue Management

Yining Wang, University of Texas at Dallas, Richardson, TX, United States, Sentao Miao

This paper proposes a practically efficient algorithm with optimal theoretical regret which solves the classical network revenue management (NRM) problem with unknown, nonparametric demand. Over a time horizon of length T, in each time period the retailer needs to decide prices of N types of products which are produced based on M types of resources with unreplenishable initial inventory. When demand is nonparametric with some mild assumptions, Miao and Wang (2021) is the first paper which proposes an algorithm with O(poly(N,M,ln(T))T‾‾√) type of regret (in particular, Õ (N3.5T‾‾√) plus additional high-order terms that are o(T‾‾√) with sufficiently large T≫N). In this paper, we improve the previous result by proposing a primal-dual optimization algorithm which is not only more practical, but also with an improved regret of Õ (N3.25T‾‾√) free from additional high-order terms. A key technical contribution of the proposed algorithm is the so-called demand balancing, which pairs the primal solution (i.e., the price) in each time period with another price to offset the violation of complementary slackness on resource inventory constraints. Numerical experiments compared with several benchmark algorithms further illustrate the effectiveness of our algorithm.

2 - Regularized Predict-Then-Optimize for Pricing with Unknown Demand Functions

Guan Wang, Rotman School of Management, Toronto, ON, Canada, Michael Albert, Max Biggs, Ningyuan Chen

<div full-size"=""><div pdfjs-viewer-outer"="">

In data-driven pricing, the firm is presented with a data set with price/demand pairs and an unknown linear demand function. The firm needs to design a price based on the data set to maximize the revenue.
We develop a novel framework to regularize the “predict-then-optimize” (PTO) approach. Our method is remarkably straightforward: we first obtain the Ordinary Least Squares (OLS) estimator, and then adjust it by multiplying with a data-driven factor, λ, where λ > 1. As a result, the proposed price is less than the price obtained from PTO. We show that this price always outperforms the price obtained from PTO in terms of the expected revenue when the data size increases. Our numerical results further confirm that this regularized price surpasses the PTO price even in scenarios with limited data. Additionally, unlike traditional
regularization approaches in linear models such as ridge regression or LASSO, our regularization inflates β instead of shrinking it toward zero. It suggests the complexities introduced by the optimization phase in the classical estimation process.

3 - Advanced Reservation Problem with Reusable Resource Under Two TIME Scales

Yun-Tung Kuo, Duke University, Durham, NC, United States, Yehua Wei, Cong Shi

We study a general online reservation model, where a decision maker attempts to maximize the total revenue endowed with limited reusable resources by accepting or rejecting advanced reservation requests. In our model, customer requests arrive continuously over time, but services to start and end on a daily basis. For this two time scales model, we design an online algorithm for the decision maker and show that the algorithm achieves asymptotic optimality under mild assumptions.

4 - Beyond Profit: Resource Pricing for Social Impact and Financial Viability

Xu Sun, University of Miami, Miami, FL, United States

Motivated by social enterprises (SE) that offer affordable and scalable reusable products or services, we consider a dynamic pricing problem faced by an SE managing various resources, each with a fixed reusable capacity or initial inventory. Price-sensitive customers arrive over time, each requesting a unit of a specific resource. When the rental ends, the resource is released and becomes available for future demand. The SE aims to optimize long-term social value while ensuring that the long-run average revenue meets or exceeds a specified threshold. We develop heuristics that solve the problem asymptotically. Numerical experiments show that the proposed solutions are highly effective.

1 - Mechanism for Decision-Aware Collaborative Federated Learning: a Pitfall of Shapley Values

Meng Qi, Cornell University, Ithaca, NY, United States, Mingxi Zhu

This paper investigates mechanism design for decision-aware collaboration via federated learning (FL) platforms. Our framework consists of a digital platform and multiple decision-aware agents, each endowed with proprietary data sets. The platform offers an infrastructure that enables access to the data, creates incentives for collaborative learning aimed at operational decision-making, and conducts FL to avoid direct raw data sharing. The computation and communication efficiency of the FL process is inherently influenced by the agent participation equilibrium induced by the mechanism. Therefore, assessing the system's efficiency involves two critical factors: the surplus created by coalition formation and the communication costs incurred across the coalition during FL. To evaluate the system efficiency under the intricate interplay between mechanism design, agent participation, operational decision-making, and the performance of FL algorithms, we introduce a multi-action collaborative federated learning (MCFL) framework for decision-aware agents. Under this framework, we further analyze the equilibrium for the renowned Shapley value based mechanisms. Specifically, we examine the issue of false-name manipulation, a form of dishonest behavior where participating agents create duplicate fake identities to split their original data among these identities. By solving the agent participation equilibrium, we demonstrate that while Shapley value effectively maximizes coalition-generated surplus by encouraging full participation, it inadvertently promotes false-name manipulation. This further significantly increases the communication costs when the platform conducts FL. Thus, we highlight a significant pitfall of Shapley value based mechanisms, which implicitly incentivizes data splitting and identity duplication, ultimately impairing the overall efficiency in FL systems.

2 - Platforms for Efficient and Incentive-Aware Collaboration

Mingda Qiao, University of California, Berkeley, Berkeley, CA, United States, Nika Haghtalab, Kunhe Yang

Collaboration is crucial for reaching collective goals. However, its effectiveness is often undermined by the strategic behavior of individual agents -- a fact that is captured by a high Price of Stability (PoS) in recent literature [Blum et al., 2021]. Implicit in the traditional PoS analysis is the assumption that agents have full knowledge of how their tasks relate to one another. We offer a new perspective on bringing about efficient collaboration among strategic agents using information design. Inspired by the growing importance of collaboration in machine learning (such as platforms for collaborative federated learning and data cooperatives), we propose a framework where the platform has more information about how the agents' tasks relate to each other than the agents themselves. We characterize how and to what degree such platforms can leverage their information advantage to steer strategic agents toward efficient collaboration.

Concretely, we consider collaboration networks where each node is a task type held by one agent, and each task benefits from contributions made in their inclusive neighborhood of tasks. This network structure is known to the agents and the platform, but only the platform knows each agent's real location. We employ private Bayesian persuasion and design two families of persuasive signaling schemes that the platform can use to ensure a small total workload when agents follow the signal. The first family aims to achieve the minmax optimal approximation ratio compared to the optimal collaboration. The second family ensures per-instance strict improvement compared to full information disclosure.

3 - Estimating and Incentivizing Imperfect-Knowledge Agents with Hidden Rewards

Ilgin Dogan, INSEAD, Fontainebleau, France, Zuo-Jun Shen, Anil Aswani

As opposed to many principal-agent models, incentive providers in practice often cannot observe the reward realizations of incentivized agents. This information asymmetry challenges the principal to lead the selfish agent by solely watching their actions, which becomes even more challenging when these actions subject to the agent's learning uncertainty. We explore this practically relevant scenario of repeated adverse selection game within a multi-armed bandit framework and jointly address: i) the consistent estimation of the agent's rewards from bounded continuous spaces, and ii) the provision of adaptive, data-driven incentives that achieve low-regret for the principal.

4 - Building Collaborative Intelligence

Sai Praneeth Reddy Karimireddy, UC Berkeley, Berkeley, CA, United States

How do we build ML systems that put the interests of users and society front and center? This talk will explore the potential of **collaborative learning (CL)** for such user-centric ML, drawing on some pilot projects with Doctors Without Borders and the Cancer Registry of Norway. We show how CL techniques such as decentralized and federated learning can allow us to train ML models without the users sacrificing their privacy or ownership and control over their data. Yet for these systems to truly succeed, two fundamental challenges must be confronted. These systems need to be efficient and **scale to massive networks,** and manage and resolve the **conflicting goals** of the participants. We will discuss how tools from optimization, statistics, and economics can be leveraged to address these challenges.

Optimization Under Uncertainty: Pricing, Inventory, and Learning

Invited Session

Revenue Management and Pricing

Chair: Jinzhi Bu, The Hong Kong Polytechnic University, Hong Kong, N/A

Co-Chair: Lei Li, Hong Kong Polytechnic University, M507n, The Hong Kong Polytechnic University, Hong Kong, N/A

1 - Randomized Robust Price Optimization

Xinyi Guan, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, Velibor Misic

The robust multi-product pricing problem is to determine the prices of a collection of products so as to maximize the worst-case revenue, where the worst case is taken over an uncertainty set of demand models that the firm expects could be realized in practice. A tacit assumption in this approach is that the pricing decision is a deterministic decision: the prices of the products are fixed and do not vary. In this paper, we consider a randomized approach to robust pricing, where a decision maker specifies a distribution over potential price vectors so as to maximize its worst-case revenue over an uncertainty set of demand models. We formally define this problem – the randomized robust price optimization problem – and analyze when a randomized price scheme performs as well as a deterministic price vector, and identify cases in which it can yield a benefit. We also propose two solution methods for obtaining an optimal randomization scheme over a discrete set of candidate price vectors based on constraint generation and double column generation, respectively, and show how these methods are applicable for common demand models, such as the linear, semi-log and log-log demand models. We numerically compare the randomized approach against the deterministic approach on a variety of synthetic and real problem instances; on real data instances derived from a grocery retail scanner dataset, the improvement can be as high as 92%.

2 - Optimizing Rarity: the Economics of Blind Boxes with Random Items

TAOJIE QIN, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Ming Hu, Shreyas Sekar

Blind box selling is a novel selling mechanism where buyers purchase sealed packages containing unknown items, with the chance of uncovering rare or special items. To unravel the economic motivation behind blind boxes, we propose a stylized model encapsulating the core trade-offs sellers face when designing a blind box package, including price and drawing probability. The model distinguishes between two types of items: regular and special, with the latter valued higher by customers due to its rarity. The customers' marginal utility from opening the blind box decreases with each unique item received, whether regular or special, but remains unchanged if they receive a duplicate item. Naturally, customers cease purchasing when the expected marginal utility becomes negative. We compare blind box selling with traditional separate selling in terms of optimal profit, sales volume, and price. Our findings indicate that item heterogeneity and rarity are necessary for the success of blind box selling. Surprisingly, we show that blind boxes are more profitable in extreme scenarios where the manufacturing costs are either low or high. We also find that blind boxes perform better when customers are highly status-seeking. However, our study also illustrates that blind boxes are not a panacea and that the seller has to deploy them carefully, especially when manufacturing costs are neither high nor low. To examine the robustness of our results, we consider cases such as endogenous supply and customer heterogeneity.

3 - Learning in Lost-Sales Inventory Systems with Stochastic Lead TIMES and Random Supplies

Jiameng Lyu, Tsinghua University, Beijing, China, People's Republic of, Xin Chen, Shilin Yuan, Yuan Zhou

Supply uncertainty, characterized by stochastic lead times and random supply quantities, has attracted increasing attention from academia, industries, and governments, particularly in the aftermath of the COVID-19 pandemic. In this paper, we consider the problem of managing lost-sales inventory systems with general supply uncertainty: stochastic lead times and random supplies. Unlike the previous studies, we assume the decision maker has no prior information on the stochastic demand and supply. We propose the first provably effective learning algorithm for inventory management problems with censored demand and supply data under general supply uncertainty. Then we establish a regret of $O(L+\mathrm{poly}(L')\sqrt{T})$ for this learning algorithm compared to the best constant-order policy, where L’ is the upper bound of the random part and L is the deterministic part of the stochastic lead times. Due to the complicated nature of the considered inventory systems, this problem exhibits three primary technical challenges: the non-convexity of cost function, the establishment of stability for inventory systems under constant-order policies, and the accurate estimation of long-run average costs. We overcome these challenges through novel approaches, some of which are of independent interest. We also conduct numerical experiments to demonstrate the effectiveness of our algorithm.

4 - Bayesian Dynamic Pricing and Subscription Period Selection with Unknown Customer Utility

Yuan-Mao Kao, Baruch College, The City University of New York, New York City, NY, United States, Bora Keskin, Kevin Shang

We consider a provider offering a subscription service to customers over a planning horizon. The customers decide whether to subscribe according to a utility model. The provider has a prior belief about the customer utility model and updates its belief based on the transaction data of new customers and the usage data of existing subscribers. The provider aims to minimize its regret - the expected profit loss relative to a clairvoyant who knows the customer utility model. To analyze regret, we first study the clairvoyant's full-information problem, noting that the resulting dynamic program suffers from the curse of dimensionality. We characterize the optimal policy for the full-information problem via a customer-centric approach that balances the provider's immediate and future profits from a customer. When the provider does not have full information, we find that the simple and commonly used certainty-equivalence policy exhibits poor performance. We illustrate that this can be due to incomplete or slow learning but can also occur because of offering a suboptimal contract with a long subscription period in the beginning. We develop an adaptive learning policy, namely the information-threshold policy, that focuses on learning until the provider's accumulated information exceeds a chosen threshold. We show that this policy achieves asymptotically optimal performance with its regret growing logarithmically in the planning horizon. Our results indicate that offering a long subscription period could be costly when the provider knows little about the customers' usage and the service cost is uncertain.

5 - Online Learning Algorithms for Multi-product Inventory Systems with Shipping Costs

Liutao YANG, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, Shining Wu

We consider the inventory optimization problem of an e-commerce firm that sells two products with unknown correlated demand where sequentially arriving customers may demand either or both products. The firm uses partial fulfillment in the way that items requested in an order are shipped via one package if they are all available or are delivered by multiple sequential shipments otherwise. We formulate the problem, analyze the optimal inventory decisions when the firm has full demand information, and develop machine learning-based algorithms for online optimization of the inventory decisions when the information is unknown and needs to be learned. These algorithms are proven efficient and effective, with a tight regret bound of $\Omega(\sqrt{T})$. We also conduct numerical experiments, highlighting the impact of incorporating shipping costs into inventory decision-making.

1 - Bi-LSTM for PV Power Forecasting: A Novel Approach for Grid Integration with EV Charging

Mengyao He, IE Business School - IE University, Madrid, Spain, Konstantina Valogianni

Photovoltaic power is one of the widely deployed renewable energy resources. However, the climate-dependent nature of photovoltaic (PV) power makes the energy generation intermittent and volatile. This intermittency could be problematic, especially for those who need a stable and reliable grid. In addition, this renewable energy could be coupled with electric vehicle charging, leading to reduced CO_2 emissions. We proposes a novel approach for forecasting photovoltaic (PV) generation using Bi-directional Long Short-Term Memory (Bi-LSTM) neural networks. Bi-LSTM's strength in handling sequential data, such as time-series data and textual data, allows for accurate predictions of PV power based on historical weather conditions. Furthermore, we explore the integration of a stochastic optimization electric vehicle (EV) charging model with the prediction system. This combined framework aims to achieve a balance between maximizing renewable energy usage and offering flexibility in EV charging schedules.

2 - Advanced Signal Decomposition Analysis and Anomaly Detection in Photovoltaic Systems

mahya qorbani, Georgia Institute of Technology, Atlanta, GA, United States, Kamran Paynabar

With the rapid expansion of large-scale photovoltaic (PV) plants, it is paramount for solar stakeholders to understand the reliability and efficiency of their plants to inform maintenance decisions, increase production, and understand the design factors that impact performance. Diagnosing underperformance in PV plants is challenging due to the relatively few monitoring points with respect to the large geographic footprint of the plant. This study introduces a cutting-edge method that transforms the analysis and management of key factors influencing PV plant performance, including performance loss rate (PLR), recoverable soiling, and major system changes. Identifying these factors is critical for deriving actionable insights. Leveraging advanced analytical techniques such as wavelet transformation, robust regression, and extreme point analysis, this approach provides a nuanced understanding of these factors. This method has been tested across two synthetic datasets and one real dataset, consistently surpassing existing benchmarks by achieving a lower median mean absolute error and reduced error variability across all comparable components.

3 - Balancing Energy Access and Clean Energy Access: Evaluating The Marginal Benefits Of Rooftop Solar PV Policies

Afsal Najeeb, IIT Bombay, Mumbai, India, Anand Rao

Policy incentivesaimed at encouraging offtake of Rooftop Solar PV (RSPV) systems by residential consumers are common in most countries. These incentives operate in the midst of policies on pricing, tariff subsidies and varying levels of solar yield in different parts of the country. The paper attempts to understand the economic viability of Rooftop Solar PV (RSPV) systems for residential consumers in India. Put simply, it aims to answer if it makes economic sense for a residential consumer to install RSPV systems and understand the conditions under which the investment becomes profitable. Load profiles of consumers drawn from different parts of the country with different levels of self consumption were obtained using smart metering data. The analysis shows that state level policies like the price of electricity, feed in tariff and availability of subsidies play a critical role in determining the economic viability of RSPV systems. An interesting effect of conflicting effects of energy equity policies and renewable energy promotion policies are observed. We find that optimally sized RSPV systems can lead to significant net present economic benefits of up to USD 1800 per year and a reduction of cost of levelized per unit cost of electricity by up to 45%. Capital subsidy remains critical to the economic viability of RSPV systems, even at high levels of consumption. Lack of proportionate benefits of export of electricity indicate that the present policy environment encourages offsetting of self-consumption with self-generation but stops short of encouraging export of electricity for economic benefit.

4 - Poverty Alleviation through Solar Energy Systems: Bridging Gaps for a Sustainable Future

Yagmur Arioz, Ankara Yıldırım Beyazıt University, Ankara, Turkey, Abdullah YILDIZBASI, Joseph SARKIS

Solar energy systems improve the quality of life by providing access to clean energy, stimulating economic development, and alleviating poverty, thereby contributing to the achievement of sustainable development goals. This study deals with the co-benefit theory and ecological modernization theory, which offer different perspectives for understanding the impacts and strategies related to the integration of solar energy into efforts aimed at poverty alleviation. By providing a reliable and renewable energy source, solar energy systems can reduce energy costs for low-income households, improve health outcomes by decreasing reliance on harmful traditional fuels, and enhance educational opportunities through better lighting and access to technology. Furthermore, the adoption of solar energy systems can create job opportunities in installation, maintenance, and manufacturing, thereby fostering economic growth. Despite these benefits, there are several critical gaps that hinder the widespread adoption and effectiveness of solar energy systems in poverty alleviation. This study addresses these gaps in the implementation of solar energy systems for poverty alleviation.

5 - Circular Economy in Solar PV: Analyzing the 10Rs through Stakeholder Theory

Yagmur Arioz, Ankara Yıldırım Beyazıt University, Ankara, Turkey, Abdullah YILDIZBASI, Ibrahim Yilmaz

The solar PV supply chain has recently surged in importance for global clean energy transitions, crucial for meeting sustainable development goals. This shift is driven by the principles of the circular economy, which are integral for enhancing energy efficiency, prolonging the life of solar panels, reducing waste, minimizing value loss, and achieving sustainability targets. To meet these goals, it's vital to improve stakeholder interactions, communication, and collaboration within the solar PV supply chain. However, there is a noticeable gap in the literature regarding the evaluation of the 10R circularity targets within the solar PV supply chain from the perspective of stakeholders. This study aims to address this gap by examining the roles and interactions of solar PV stakeholders in achieving circularity goals, offering managerial insights through the lens of stakeholder theory and employing a hybrid multi-criteria decision-making approach based on a real-world case. The results indicate that stakeholder theory is a robust framework for supporting the development and sustainability of circular supply chains in the solar PV sector.

1 - Real-time Adaptation for Time-series Signal Prediction using Label-aware Neural Processes

Seokhyun Chung, University of Virginia, Charlottesville, VA, United States, Raed Al Kontar

Building a predictive model that rapidly adapts to real-time condition monitoring (CM) time-series data is critical for engineering systems/units. Unfortunately, many current methods suffer from a trade-off between representation power and agility in online settings. For instance, parametric methods that assume an underlying functional form for CM signals facilitate efficient online prediction updates. However, this simplification leads to vulnerability to model specifications and an inability to capture complex signals. On the other hand, approaches based on over-parameterized or non-parametric models can excel at explaining complex nonlinear signals, but real-time updates for such models pose a challenging task. In this paper, we propose a neural process-based approach that addresses this trade-off. It encodes available observations within a CM signal into a representation space and then reconstructs the signal's history and evolution for prediction. Once trained, the model can encode an arbitrary number of observations without requiring retraining, enabling on-the-spot real-time predictions along with quantified uncertainty and can be readily updated as more online data is gathered. Furthermore, our model is designed to incorporate partial information on qualitative factors (e.g., missing labels) from individual units. This integration not only enhances individualized predictions for each unit but also enables joint inference for both signals and their associated labels. Numerical studies on both synthetic and real-world data in degradation modeling highlight the advantageous features of our model in real-time adaptation, enhanced signal prediction with uncertainty quantification, and joint prediction for labels and signals.

2 - A data-driven approach to improving student perceptions of undergraduate analytics courses

Baback Vaziri, James Madison University, Harrisonburg, VA, United States, Jacob Sanzano, Luis Novoa, Gizem Atav

As educators, we have different approaches to improve student experiences in our classroom. Oftentimes, however, experiences can be shaped by their perceptions going into the class. In this study, we collect data to understand perceptions of students coming into an undergraduate business course in analytics – specifically, management science. Given the rising importance of analytics in the business field, and the fact that employers are more and more looking for employees with skills related to data analytics, it is important for students to not only be successful in analytics courses, but to also have a positive experience. Upon developing and administering a survey to examine various components of students' perceptions going into analytics courses, we used factor analysis to identify the major factors contributing to these perceptions. The snapshot of the current landscape allows us to make decisions to incorporate changes to the course and help improve the experience for students going forward, with the goal that these decisions will help improve the perceptions of future students going in the course.

3 - Unsupervised Multi-Source Domain Adaptation in Cross-Machine Scenario with Mixed Heterogeneity

Yujun Yang, Yonsei University, Seoul, Korea, Republic of, Yongmin Kim, Hyunsoo Yoon

Rotating machinery is pivotal in industrial operations, where deep learning-based automated fault diagnosis offers significant advantages on system maintenance. With this premise cross-domain and cross-machine adaptation techniques are on a rapid research, where cross-domain adaptation deals with various load conditions and cross-machine adaptation aims to synchronize heterogeneous data collected from various machines which is more challenging. Multi-source based domain adaptation has garnered significant attention in research endeavors aimed at optimizing adaptation between source and target domains. However current multi-source based adaptation researches only deals with the scenario where multi sources and target shares the same heterogenity i.e in cross-domain scenario multi sources are given as various load condition and target as additional load condtion and in cross-machine scenario as various machines and additional machine. We claim that the intermediate scenario between aforementioned two can be more realistic where multi-source is given as various load and the objective target is given as additional machine. So we propose multi source unsupervised domain adaptaion method under mixed heterogeniety composed of multiple source under various load condition and target with additional machine with notable extent of domain gap.

4 - Analyzing a capacitated vehicle routing problem variant : Insights from approximations and mathematical analytics

Hyungjoo Cha, Korea University, Seoul, Korea, Republic of, Taesu Cheong

In this talk, we review the analysis of the capacitated vehicle routing problem in approximation and mathematical analytic point of views. Specifically, we formulate the CVRP-variant model for reverse logistics, where trucks are selectively dispatched to collect the parcels required. Apart from the mathematical formulation, we also execute the bound analysis using Beardwood-Halton-Hammersley theorem, which approximates the total tour length of a TSP tour with specific conditions. Moreover, with the modification of the well-known alpha-approximation algorithms, we provide a viable solution framework of the proposed algorithm. We review the solutions of the mathematical mode, approximation algorithms and the derived bounds correspondingly and derive the managerial insights. Our findings promise to inform decision-makers in logistics optimization, offering strategies to enhance efficiency and cost-effectiveness in transportation operations.

Decision Analysis in Public Health and Biomedicine

Invited Session

Decision Analysis Society

Chair: Marie-Laure Charpignon, MIT, Cambridge, MA, United States

1 - Novel Digital Data Sources for Health Policy Research

Maimuna Majumder, Harvard Medical School & Boston Children's Hospital, Boston, MA, United States

In this talk, Prof. Majumder will discuss the utility of novel digital data sources for health policy research, with a focus on how sociopolitics —and politicians—have impacted our collective health during the COVID-19 pandemic. She will provide a brief overview of three of her lab's recent papers, covering the following interconnected topics: (1) Smartphone Mobility Data for National & State-Level Health Policy Evaluation; (2) Search Query & News Media Data for Monitoring Socioepidemic Misinformation; and (3) Social Media Data for Assessing Responses to Governmental Health Guidance. More specifically, she will focus on the impacts of (1) paid sick leave on compliance with non-pharmaceutical interventions in the US; (2) President Trump's remarks regarding the off-label use of disinfectants as a COVID-19 therapeutic; and (3) the CDC's mask guidance on the public's trust in American health agencies.

2 - Designing Trustable Risk-Based Intervention Strategies in an Infectious Disease Crisis

Andrew Perrault, The Ohio State University, Columbus, OH, United States

In an infectious disease crisis, planning interventions is a multi-objective problem that requires trading off among preventing the spread of disease, reducing the individual liberties of the uninfected, and financial and resource cost. In addition, intervention plans need to respect the information available to decision makers and be simple enough to be executed in a distributed fashion. I will present recent work where we take a cluster-based view that mirrors the information available to contact tracers. Using a simple agent-based model that can be updated as more detailed pathogen information becomes available, we develop an automated optimization approach leveraging deep and reinforcement learning that produces simple intervention strategies and achieves better objective values by about 25% compared to baselines.

3 - Monitoring Events in Large-Scale Public Health Data Streams

Ananya Joshi, Carnegie Mellon University, Pittsburgh, PA, United States

Traditional monitoring approaches were not designed to handle the volume and complexity of modern data. Their limitations are particularly apparent in the public health setting, where monitoring data volumes have increased exponentially and include incomplete, noisy, and non-stationary data subject to multiple forms of seasonality, censorship, and lags (revisions) that mask potential events like outbreaks and data quality issues. Our research addresses this gap by developing and implementing scalable monitoring methods tailored to handle the complexities of this modern monitoring setting. We present our novel approach, including new monitoring methods and frameworks that process and analyze vast amounts of health data in real-time to provide experts with actionable intelligence. Over the past 18 months, our approach has been deployed in a real-world public health setting and has demonstrated a 53x increase in monitoring efficiency. On average, over 200 events are identified weekly so data users can take informed decisions. This practical application opens new avenues for research in scalable monitoring techniques across domains.

4 - Regression discontinuity designs for evaluating AI/ML-enabled interventions in healthcare: Lessons learned from evaluations of two real-world deployments

Ben Marafino, Kaiser Permanente Division of Research, Oakland, CA, United States, Robert Gallo, Vincent Liu

While randomized trials are currently the gold standard for evaluating AI/ML-enabled interventions in health care, their implementation is often stymied by several factors. Integrating randomization into live clinical workflows frequently proves challenging, owing to complexities involved in both design and implementation. In addition, the oversight and compliance requirements associated with randomized trials, even “pragmatic” trials, can be burdensome. Given these limitations of randomized experiments in healthcare settings, regression discontinuity (RD) designs offer a credible alternative and turn out to be uniquely well-suited for analyses of the effectiveness of such AI/ML-enabled interventions. The RD design generally requires few assumptions and is capable of providing strong evidence without the need for randomization. Moreover, the RD design can be applied retrospectively, or it may form the bedrock of a planned analysis in instances where randomization proves infeasible. In this talk, I will briefly provide an overview of the unique features of the RD in the context of AI/ML-driven interventions, and present examples where it was successfully used to evaluate the effectiveness of large-scale AI/ML deployments at Kaiser Permanente and Stanford Health Care.

5 - New Approaches to Equitable Intervention Planning to Improve Engagement and Outcomes in a Digital Health Program

Yugang Jia, NA, Winchester, MA, United States

Background: Digital health programs provide individualized support to patients with chronic diseases and their effectiveness is measured by the extent to which patients achieve target individual clinical outcomes and the program’s ability to sustain patient engagement. However, patient dropout and inequitable intervention delivery strategies, which may unintentionally penalize certain patient subgroups, represent challenges to maximizing effectiveness. Therefore, methodologies that optimize the balance between success factors (achievement of target clinical outcomes and sustained engagement) equitably would be desirable, particularly when there are resource constraints.

Objective: Our objectives were to propose a model for digital health program resource management that accounts jointly for the interaction between individual clinical outcomes and patient engagement, ensures equitable allocation as well as allows for capacity planning, and conducts extensive simulations using publicly available data on type 2 diabetes, a chronic disease.

Methods: We propose a restless multiarmed bandit (RMAB) model to plan interventions that jointly optimize long-term engagement and individual clinical outcomes (in this case measured as the achievement of target healthy glucose levels). To mitigate the tendency of RMAB to achieve good aggregate performance by exacerbating disparities between groups, we propose new equitable objectives for RMAB and apply bilevel optimization algorithms to solve them. We formulated a model for the joint evolution of patient engagement and individual clinical outcome trajectory to capture the key dynamics of interest in digital chronic disease management programs.

Decision Analysis for an Equitable Energy Future

Invited Session

Decision Analysis Society

Chair: Sheng Lun Cao, Carnegie Mellon University, Pittsburgh, PA, United States

1 - Incorporating a Value of Lost Load Function In Equity-Centric Energy Systems Modeling

Sheng Lun Cao, Carnegie Mellon University, Pittsburgh, PA, United States

Energy system reliability is a key consideration in achieving energy equity for long-term grid-level systems planning, especially since long-duration outages due to increasing extreme weather impacts population groups differently. Incorporating equity-centric reliability considerations into energy systems modeling requires a re-evaluation of the traditional least cost optimization paradigm these models are typically based on. A key aspect of this incorporation is understanding people's preference heterogeneity and trade-offs for reliability. This relationship between people and reliability can be captured through the Value of Lost Load (VoLL), an estimated amount a customer is willing to pay to avoid a disruption to their electricity service. While typically a point estimate in $/kWh units, VoLL can be represented as a function relative to outage duration through the Customer Damage Function (CDF). We consider a) how a VoLL function can be used in reliability assessment of long-term grid-level systems planning, and 2) how the heterogeneous functional forms of VoLL can impact grid reliability at different spatial resolutions.

2 - Evaluating Equity Impacts of Vehicle-to-Grid Integration for the US Virgin Islands

Ogechi Vivian Nwadiaru, University of Massachusetts-Amherst, Amherst, MA, United States, Todd Levin, Erin Baker

This research integrates equity considerations into Vehicle to Grid (V2G) deployment, using the US Virgin Islands (USVI) as a case study. As distributed energy resources grow, vehicle-to-grid technologies can facilitate the transition to renewable energy by using electric vehicles as storage assets to mitigate potential renewable curtailment and offer resilience during periods of extreme weather events. Without deliberate attention to equity, V2G risks exacerbating disparities in access, affordability, and environmental justice. If done right, it has the potential to bring benefits to marginalized communities.

We investigate the grid and equity impacts of leveraging electrified public transit EV charging for renewable energy integration in a historically marginalized setting, focusing on the mid-transition. The study takes a two-prong approach, first, we optimize the charging schedule for public fleet EV deployment and V2G operational strategies and simulate the implications for system costs and reliability while also capturing key equity metrics. We then further iterate with community stakeholders to delve deep into unaddressed equity concerns.

To conduct this analysis we use the Argonne Low-carbon Electricity Analysis Framework (A-LEAF) as an integrated production cost model and reliability assessment toolkit. We demonstrate our approach through a case study application of the IEEE GMLC Reliability Test System (RTS-GMLC), which has been further calibrated to capture key parameters that characterize the USVI, such as the existing generation portfolio and demand profiles. Through this framework, we evaluate multiple V2G implementation and operational strategies and assess tradeoffs and complementariness across the stakeholder-derived metrics for localized reliability, cost, and mobility autonomy.

3 - Energy Justice Constrained Power System Dispatch and Planning

Juliette Ugirumurera, National Renewable Energy Laboratory, Golden, CO, United States

Power plants are one of the main sources of air pollution. Our current grid modeling capabilities are unable to represent air pollution and health impacts from the electricity industry in the optimization. Therefore, we propose a novel approach to link a power system model (Sienna) with a high-fidelity air quality model (known as SCICHEM) and human health impacts modeling tool (known as BenMAP) to assess the impacts of operating power plants on health and damage costs. This linkage will help us develop a module to evaluate the environmental justice impacts on different demographic groups, especially vulnerable communities. It will also help inform better decisions in capacity expansion models for future systems to avoid unfairly burdening certain communities. A case study will demonstrate modeling capabilities and generate example analysis for regions with at-risk communities. This new capability can be used by system operators, researchers, and other entities to better plan and operate energy systems that are just for all and to understand the implications of our current operating power system on specific communities.

4 - Advancing equitable household and community benefits through energy storage

Jessica Kerby, PNNL, Salem, OR, United States, Bethel Tarekegne

As energy prices rise and climate change brings more extreme and frequent days of heating and cooling, households must allocate more of their income to energy bills, increasing their energy burden. Many strategies are employed to alleviate high energy burden, such as weatherization, energy efficiency, and energy storage and rooftop solar, though the benefits of each scale based on factors such as climate, housing characteristics, and energy behaviors. In addition, federal and state decarbonization goals have led to numerous financial incentives and policies designed to increase access and adoption of renewable energy systems. In combination with the declining cost of both solar photovoltaic and battery energy storage systems and rising electric utility rates, residential renewable adoption has become more favorable than ever. However, not all states provide the same opportunity for cost recovery, and the complicated and changing policy and utility landscape can make it difficult for households to make an informed decision on whether to install a renewable system. This work explores the idea of providing a targeted approach to energy burden reduction, based on household conditions, climate, and policy. For households considering renewable adoption, this work also discuss the relevant factors that influence renewable system performance and payback as a guide to help navigate the policy, utility rate structures, system, and financial considerations required for rooftop solar and energy storage.

5 - Locational Marginal Burden: Equity embedded in optimal power flow

Amanda West, Georgia Institute of Technology, Atlanta, GA, United States, Samuel Talkington, Rabab Haider

The fair distribution of benefits in electric power systems is a pertinent energy policymaking problem; however, energy justice and equity efforts cannot be easily quantified in existing power system engineering studies. To incorporate justice and equity into operations and planning problems, we propose a metric termed *locational marginal burden* (LMB). The LMB metric provides an interface between energy burden -- well-studied in energy pricing equity -- and the optimal power flow problem -- used ubiquitously in electricity market clearing and resource dispatch -- by leveraging tools from differentiable optimization. In this work we present the LMB metric which describes the marginal impact of nodal demand in the transmission system to the energy burden experienced by customers, similar to traditional Locational Marginal Prices (LMP) used in transmission wholesale electricity markets. In deriving the LMB metric, we can assess the impact to energy burden of a customer by an increase in both local demand (at the same transmission node) as well as network-wide effects (at other transmission nodes). This presentation introduces the LMB metric, preliminary investigation of LMB-integrated planning decisions, and future directions of research in tariff design and integrated resource planning.

Digital Content and Platform Strategies

Contributed Session

Chair: Wei Lu, University of Science and Technology of China, 96 Jinzhai Rd, Hefei, 230026, China, People's Republic of

1 - Subscription Mix: Menu Pricing in Two-Sided Media Platform Competition

Yunhyoung Kim, University of Minnesota Twin Cities, Minneapolis, MN, United States

This article studies the impact of subscription mix, "consumers' multi-homing behaviors based on video service platforms' menu pricing strategies", in two-sided media platform competition. Recently, there are huge portions of consumers who subscribe to more than one video streaming service. Platforms like Netflix and YouTube have introduced varied subscription models—including premium, ad-supported, and free access—to not only increase their subscriber base but also to appeal to a broader range of advertisers. The study questions the efficacy of such strategies, considering the unpredictability of consumer subscription combinations and the potential decline in advertising revenue if platforms fail to target unique consumer segments effectively. Given these dynamics, two different media platforms are considered: an advertising-focused media platform and a subscription-focused media platform. An analytical model, grounded in two-sided platform competition literature, is employed to explore these phenomena.

Key findings reveal that consumers' mix of subscriptions encourage platforms to adopt asymmetric menu pricing strategies, allowing them to mitigate intense competition on both the consumer and advertiser sides. These strategies are found to be largely dependent on the marginal utility derived from multi-homing. There is an identified optimal level of marginal utility increase from multi-homing that enables platforms to diversify subscription plans and maintain a competitive edge, resulting in mutual benefits for all involved up to certain thresholds. The advantageous effects diminish as the marginal value from multi-homing changes, presenting a critical balance that platforms must navigate.

2 - Video Views or View Time: Managing Platform Compensation for Content Creators

Xu Zhang, Fudan University, Shanghai, China, People's Republic of, Hongbo Zha, Yinuo Tang, Yifan Dou

For content platforms, compensating content creators for their contributions is pivotal to the success of a thriving ecosystem. We use video content platforms such as YouTube, TikTok, and Bilibili as examples in this paper. Traditionally, compensation has been based on the count of Video Views (VV), which is directly linked to the platform's revenue from advertising services. However, to incentivize long-video creators, this paper evaluates a new compensation model based on View Time (VT), which is emerging in practice. The existing literature has not sufficiently examined how incentive compensation schemes should accommodate view time, which represents a distinct dynamic within the creator economy. We develop a game-theoretical model to investigate whether transitioning from VV to VT is beneficial for the platform, creators, and viewers.

The VV-VT transition helps resolve the traditional conflict of compensating long-video creators, specifically sharing less revenue in the time-constrained viewers' market while incentivizing creators. Additionally, the VV-VT transition can enhance the relative attractiveness of long videos, which previously faced a disadvantage compared to short videos, thereby altering the competitive structure. This enhancement is, however, negatively affected by the proportion of time-constrained viewers. While insufficient or moderate enhancement can intensify the competition among creators, excessive enhancement will conversely mitigate the competition. Therefore, a higher proportion of long-video creators and a higher proportion of time-constrained viewers increase the profitability of the VV-VT transition. Furthermore, with a significantly large proportion of time-constrained viewers, we find that the transition can lead to a Pareto improvement.

3 - Content Creation, Competition and Selective Promotion of Apps

Aditya Karanam, National University of Singapore, Singapore, Singapore, Ashish Agarwal, Anitesh Barua

It is well documented in the literature that selective promotion of mobile applications in the app store has cascading effects on the demand and design of a range of non-promoted applications. However, the nature of influcence of these spillover effects on the category's overall demand and competition is not clearly known, especially in the context of app econonomy. By utilizing iOS App Store data spanning the years 2017 to 2022, this research seeks to understand the impact of these spillover effects on the overall design and competition among applications in a given category. Our results indicate that non-promoted apps within a category become increasingly similar to the promoted apps. We also observe that while the overall demand of a category increases, this increase is majorly concentrated among a few apps. These findings underscore the significant role played the platform promotions on the design and competition of the overall ecosystem.

4 - Retailer's Information Sharing and Manufacturer's Channel Expansion in The Live-Streaming E-commerce Era

Wei Lu, University of Science and Technology of China, Hefei, China, People's Republic of, Jie Wu, Xiang Ji

Numerous manufacturers started to embrace live-streaming selling channels in addition to their pre-existing retail channels during the outbreak of COVID-19. Our work investigates a retaile's optimal strategy for sharing demand information with a manufacturer who might collaborate with a streamer to build a live-streaming selling channel. The results point out that the manufacturer's live-streaming selling channel expansion via an influencer does not necessarily harm the retailer because the retailer can free ride on the market expansion due to the social influence of the streamer. We also provide a rationale for the widespread voluntary information sharing observed in the era of live-streaming selling. The retailer can discourage or encourage the manufacturer to establish a live-streaming channel by sharing the demand information, which depends on the streamer's social influence. In addition, potential changes to information sharing policy result in several unexpected profit implications for the manufacturer, whose profit exhibits a nonmonotonic relationship to the streamer's social influence and the channel expansion cost. In other words, our results counterintuitively show that the manufacturer may suffer from cooperating with a highly influential streamer in a live-streaming channel but benefit from choosing a less influential one.

Summit - 344

Applications and Implications of Large Language Models

Contributed Session

Chair: Senyao Gu, Tsinghua University, Beijing, N/A

1 - *Examining the Impact of Reliance on LLMs on Perceived Creativity*

Jiaoping Chen, Michigan State University, East lansing, MI, United States, Laura Brandimarte, Anjana Susarla

Large Language Models (LLMs) have been increasingly integrated into a myriad of open-ended tasks, facilitating human endeavors in generating creative outputs ranging from product ideation to digital artwork. Such novel capabilities of LLMs have ushered in a new era of human-AI collaboration. Limited studies focus on the impact of reliance on AI's advice and the generative capabilities of LLMs. In this study, we address this gap using creative writing tasks. We first employ a structured experimental framework by focusing on creative writing tasks under two distinct conditions: low vs high LLM randomness. We then assess two outcome variables: perceived creativity, and likability of these narratives by conducting an online survey. This study finds that the effect of writers' reliance on AI advice on perceived creativity varies with the level of generative capabilities inherent in the LLMs (high vs. low randomness). Specifically, in contexts where LLMs generate less diverse suggestions, a higher acceptance of AI suggestions is associated with decreased perceived creativity. In contrast, when LLMs provide more diverse advice, the increasing reliance on LLMs are associated with increased creativity of work. Lastly, we further explore how the characteristics of raters could influence their perceptions of creativity.

2 - Distillation of knowledge and opinion of LLMs in an opinion dynamic framework

Lan Hoang, IBM, Warrington, United Kingdom, Michail Smyrnakis, Carol Mak

Large language models (LLMs) have emerged as a group of powerful, versatile models that can assist humans in multiple tasks. To date the focus has largely been on single LLM or a mixture of LLMs to conduct tasks. Yet, there is an implication for knowledge and bias distillation arising with LLM interactions, such as in via fine-tuning or interactions. In this work, we aim to review the current approaches of social interactions of LLMs and propose a framework to investigate the interactions using agent-based modelling. Specifically we will use the opinion dynamic experiments and equilibrium analysis to enable the study of knowledge and bias propagation. This cascading through the networks can lead to LLM clusterings and group dynamics that differ from initial training objectives. This direction will have applications in the area of AI ethics and in the real world application of LLMs in the multi-agent setting.

3 - Patterns for Co-opting Large Language Models and Knowledge Bases to Enable Smarter Decisions

Dinesh Verma, IBM Research, Yorktown Heights, NY, United States, Pawan Chowdhary, David Beymer, Swanand Kadhe, Jon Lenchner, Shiqiang Wang

While Large Language Models (LLMs) have proven themselves useful in many contexts, they also have drawbacks including hallucinations and non-repeatability. In many cases, decision making based on knowledge bases may be better from a reliability, explainability or repeatability perspective, but suffers from the high overhead required for maintaining and updating the knowledge base. In order to make smart dynamic decisions, the best approach may often consist of a hybrid approach that combines the strengths of both LLMs and knowledge bases. This combination can be done in many different ways, and results in a few distinct patterns for joint use of LLMs and Knowledge bases. In this paper, we will present and examine some of the common patterns for joint use of LLMs and knowledge bases and compare their strengths and weaknesses. Specifically, we consider the following patterns: (a) using the knowledge base as a backup mechanism for a LLM (b) using a LLM to augment a knowledge base (c) using a knowledge base to fact-check a LLM and (d) using a knowledge base to optimize inference based on LLMs, among others. We will also show the effectiveness of the patterns in solving a problem such as secure search on the Internet.

4 - Integrating Large Language Models into Production Planning: A Framework for Simulation-Based Optimization

Lennard Heuer, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of

Creating optimization models (OMs) for production planning within a simulation environment that closely replicates a real-world manufacturing setting is challenging, as these OMs often fail to encapsulate the complexity and dynamic relationships inherent in such simulations. However, OMs offer interpretability beyond numerical results alone, revealing crucial heuristics and contextual relationships essential for strategic decision-making. Large language models (LLMs) have recently surged in popularity and can now be utilized in diverse tasks, including code generation. Leveraging the capabilities of LLMs, this study presents a framework for creating customized, LLM-generated production planning OMs, using detailed simulation feedback for OM refinement. Initially, an LLM processes user input data to select or combine linear programming OMs from a preselected pool. Next, using an iterative approach, an LLM extends the OM, potentially transforming it into more complex forms such as mixed-integer nonlinear programming. The LLM thereby modifies the objective function and adds constraints focused on production, sales, inventory, and workforce strategies. Simulation feedback is used to evaluate the overall performance of the production plan derived from an OM and to enable an LLM to identify specific weaknesses detected in the simulation feedback. This allows for intelligent decisions on further LLM-generated alterations of the OM. The above-described method is embedded as a mutation in a genetic algorithm, which also utilizes population initialization, selection, and crossover to enable a global search for an optimal OM. Furthermore, OM parameters newly added through the genetic algorithm are fine-tuned for further optimized production plan performance in simulation.

5 - Utilizing Large Language Models to Elicit Human Thought Processes in Decisions under Risk

Senyao Gu, Tsinghua University, Beijing, China, People's Republic of, Chen Wang

This study performs cumulative reasoning on a large language model (LLM) to reveal the underlying thought processes based on a mixture of decision theory models. The LLM is specifically tuned to mimic human medical decisions in a large dataset of electronic health records. We first prompt the LLM to qualitatively classify if the basic arithmetic operations (including monotonicity, convexity, continuity, and isomorphism) are employed to reach the treatment decision. We then fit a mixture of decision theory models (MoT) based on the classification results to depict the thought processes quantitatively. This study extends recent advances in using deep learning methods to describe human decisions under risk, with simple lottery experimental data, to real-world decision contexts involving multi-modal data (qualitative, quantitative, texts, etc.)

Gurobi/Stukent

Invited Session

Technology Showcase

1 - Practical Guidelines for Model Improvement and Reformulation

Rodrigo Fuentes, Gurobi Optimization, Plymouth, MA, United States

In this showcase, we will share insights and lessons learned from helping Gurobi customers from a wide range of industries adjust their optimization models to improve solver performance and numerical behavior. We will look at the challenges that we see most often in LP, MIP and MINLP models, and discuss our approach and typical recommendations to help address them. We will also consider some well-known modeling “rules of thumb” and discuss how applicable they are in 2024.

2 - How Virtual Work-integrated Learning can Help Educators Overcome Today’s Instructional Challenges

Scott Carr, Stukent, Idaho Falls, ID, United States

A Stukent Simternship is a career-relevant, work-integrated learning experience that helps students connect classroom concepts to real-world tasks. In a Simternship, students become marketing managers, PR officers, entrepreneurs, SEO specialists, accountants, and more. They interact with simulated supervisors and coworkers, perform realistic tasks, and build confidence in the safety of a simulated environment.

Simternships allow students to apply new knowledge to professional problems. This level of immersion helps students encode the information they are learning in class, which allows them to transfer new concepts to real-world scenarios. All Simternships feature auto-grading and LMS integration to take the hassle out of hands-on education.

1 - Quantifying Causal Influences with Graphical Causal Models for Root Cause Analysis and Beyond

Patrick Bloebaum, AWS, Santa Clara, CA, United States

Explainability has become a critical challenge for businesses seeking to make informed decisions and drive continuous improvement. In this talk, we present domain-agnostic approaches that utilize graphical causal models to represent causal relationships within a system, enabling the quantification of direct and indirect causal influences of system components on key metrics. This allows us to move beyond mere statistical associations to gain a deeper understanding of a system. We particularly focus on novel concepts for root cause analysis that allow the identification of the underlying causes of anomalies and distribution changes by modeling the causal mechanisms that generated the data. Furthermore, we illustrate how this causal approach can be used to explain the factors influencing specific key metrics in a system, which is crucial for any critical decision-making process. The presented concepts and algorithms in the talk are readily available as open-source solutions and can be integrated into various business processes to enhance explainability, optimize systems, and drive data-driven decision-making.

2 - Brple: Bayesian Regularized Post-Hoc Local Explanations

Yuhao Zhong, Texas A&M University, College Station, TX, United States, Anirban Bhattacharya, Satish Bukkapatnam

Existing studies that focus on explaining black-box machine learning models either overlook the uncertainty in generated explanations or quantify this uncertainty inadequately. To address this gap, we propose BRPLE to explain machine learning models and obtain the distribution of feature importance using Bayesian ridge regression. We present the mathematical framework of our Bayesian approach and discuss theoretical outcomes, including the significance of the ridge parameter. Our methodology was validated through case studies on both numerical simulations and benchmark datasets. Compared to state-of-the-art methods, BRPLE offers superior accuracy in uncertainty quantification, specifically in deriving the posterior distributions and rankings of feature importance.

3 - Explainable Machine Learning for Knowledge Discovery in Advanced Manufacturing Systems

Joseph Cohen, University of Michigan, Ann Arbor, MI, United States, Eunshin Byon, Xun Huan

In recent years, machine learning has become popular for optimizing the operations of advanced manufacturing systems. These data-driven algorithms have enabled key performance indicator improvements such as reducing machine downtime, improving quality, yield, and sustainability. However, as advanced data analytics and digital twin platforms mature in the age of generative AI, there is an unmet need to critically evaluate model outputs to gauge trustworthiness. This presentation will focus on our efforts in advancing explainable anomaly detection, fault diagnosis, and prognosis of high-dimensional applications in semiconductor and aerospace manufacturing systems, as well as renewable power systems. The talk will detail an approach for semi-supervised clustering based on Shapley value analysis, with the added capability of accurately describing clusters with measurable inputs. In addition, our efforts in explaining model outputs via counterfactual explanations will be discussed. Lastly, we will describe how these techniques provide actionable insights for hypothesis generation, knowledge discovery, and synergize well with other AI application areas such as active learning and reinforcement learning.

4 - Multi-perspective Explainable Artificial Intelligence

Andrew Kusiak, University of Iowa, Iowa City, IA, United States

Explainable artificial intelligence (XAI) solutions provide insights into digital models and increase understanding and confidence in the generated results. As data-derived models become more complex, wider is scope, and cover multiple domains, interpretation of the model produced decisions becomes challenging. Such decision-making scenarios call for multi-domain expertise to design XAI systems for the deployment of models and interpretation of the predicted outcomes. An XAI solution for complex and multi-domain applications is discussed. The solution includes different modes of operations and supports user preferences.

5 - A Stochastic Method for Physics Discovery via Sparse Identification of Nonlinear Dynamics

Ridwan Olabiyi, Arizona State university, Tempe, AZ, United States, Han Hu, Ashif Iquebal

This paper introduces a novel stochastic method that leverages the Sparse Identification of Nonlinear Dynamics (SINDy) algorithm and consistent Bayesian inference to derive physics models from data. This approach not only identifies crucial dynamical terms in the system governing equations but also determines the probabilistic distributions of their coefficients, thereby producing a detailed model that accurately reflects the underlying physical processes. Our method is particularly suited for inferring the unknown governing physics of complex systems characterized by nonlinear dynamics with stochastic parameters. The proposed method not only provides a robust framework for discovering governing equation of such complex system from data but also allows for uncertainty quantification of the discovered models under varying conditions, making it an invaluable tool in machine learning frameworks for physics discovery. We evaluate the efficacy of our proposed methodology against conventional methods through benchmark datasets using simulated data from the Lotka-Volterra model, the Hudson Bay (lynx-hare) dataset, and three diverse infiltration datasets. The results shows that our method outperforms existing approaches based on standard metrics, confirming its superiority in modeling complex dynamical systems.

1 - Learning in Human&Mdash;AI Teams

Zhaohui Jiang, Carnegie Mellon University, Pittsburgh, PA, United States, Param Singh, Linda Argote

Although rapid developments in algorithms and artificial intelligence (AI) are occurring, these AI systems often do not operate fully autonomously but rather require humans and AIs to jointly make decisions. Because humans and AI systems have complementary skills and information, their joint decision making could be better than human or AI decision making alone. We refer to these collaborative decision-making units as *human—AI teams* and seek to understand the human learning process in human-AI teams, including: (1) Can humans learn how to collaborate with AI through repeated practice? (2) What factors affect this learning process? Does the interpretability of the AI collaborator impact learning, and if so, what is the optimal level of interpretability? (3) Does human independent decision-making ability matter, and how would it impact the answers to the questions above? Findings from our studies can offer policy and managerial insights (e.g., designing more effective training programs) to facilitate modern decision making with human-AI teams.

2 - Effect of Task and Temporal Attributes on Customers&Rsquo; Decisions to use Self-Service Technologies

Yinghao Zhang, University of Cincinnati, Cincinnati, OH, United States, Chia-Chun Yang

Self-service technologies (SSTs) are being increasingly implemented across various service industries, including financial, retail, and healthcare. Early research highlighted the benefits of SSTs for service organizations, emphasizing cost reduction and productivity enhancement. Recent studies have shifted their focus toward understanding the factors that motivate customers' decisions to use SSTs. These studies have primarily concentrated on the factors of customer characteristics (e.g., personality, technology attitude, self-efficacy, and prior experience) and system design (e.g., convenience, ease of use, controllability, flexibility, supportiveness, and enjoyment). However, there is still a lack of knowledge regarding situational factors that can influence customers' decisions. Hence, our study focuses on two such factors: Task Complexity and Time Pressure. This leads to our research question: How do task complexity and time pressure influence customers' preferences of using self-service technologies? To answer this question, we designed and conducted online experiments to observe people's SSTs preferences under a simulated grocery checkout environment. This research method is novel compared to the previous literature, which typically relies on scenario-based surveys to examine people's general perceptions and choices. Our study contributes to the existing literature by examining situational factors as determinants of customers' decisions to use service technology; where knowing how such factors affect customers' decisions is insightful for organizations to make better decisions about investing and allocating self-service technologies to improve operational and financial performances.

3 - Automation and Augmentation: Roles of AI in Collaborated Decision Making

Andreas Fuegener, University of Cologne, Köln, Germany, Dominik Walzner, Alok Gupta

Artificial intelligence (AI) will have a growing influence in the future of work. Human decision-makers may see significant changes in their day-to-day work as collaboration between humans and AI will become commonplace. We explore the application of AI for automation (i.e., AI performing tasks independently) and for augmentation (i.e., AI advising humans) in collaborative environments. Using an analytical model, we show that whether AI should be used for automation or for augmentation depends on different types of human-AI complementarity: The share of automation increases with higher levels of between-task complementarity, which can arise due to task-level performance differences between humans and AI. In contrast, the share of augmentation increases with higher levels of within-task complementarity, which arise due to task-based interaction between humans and AI. We include both AI roles in a task allocation framework, where an AI and humans work on a set of classification tasks to optimize performance with a given level of available human resources. We validate our framework with an empirical study based on experimental data in which humans had to classify images with and without AI support. When between-task and within-task complementarity exist, we see an interesting distribution of work pattern for optimal work configuration: AI automates relatively easy tasks, augments humans on tasks with similar human and AI performance, and humans work without AI on relatively difficult tasks. Our work provides several contributions to theory and practice and our task allocation framework showcases potential job designs in the future of work.

4 - Biases of Humans, of AI, and of Humans with AI

Tracy Jenkin, Queen's University, Kingston, ON, Canada, Yang Chen, Sam Kirshner, Anton Ovchinnikov, Meena Andiappan

Since the release of ChatGPT in November 2022, research on decision-making biases in large language models (LLMs) has rapidly proliferated. LLMs are mathematical models that represent the current frontier of Artificial Intelligence (AI), but they are trained on human data, and a consistent observation from this research is that LLMs may mirror human biases, remain unbiased, or can even display biases distinct from those of humans. Our research advances the literature by examining whether individuals change their inherent biases when interacting with AI that might be biased similarly or differently from humans. To study this question, we design a novel interactive AI experimental design paradigm and apply it to three representative biases from the literature. We show that AI biases indeed impact human decision-making and discover a new form of nudging via system prompts. Finally, we propose a new take on algorithm aversion by showing that how humans interact with AI matters for improving decision-making.

Smart Manufacturing Systems

Contributed Session

Chair: Thomas Meiren, Fraunhofer IAO, Nobelstr. 12, Stuttgart, 70569, Germany

1 - Time-Series Classification in Smart Manufacturing Systems

Mojtaba Askarzadeh Farahani, West Virginia University, Morgantown, WV, United States, Matt McCormick, Ramy Harik, Thorsten Wuest

The shift toward smart manufacturing marks a new era dominated by digital technology, significantly enhancing data collection capabilities through advancements in sensing technologies. Central to these smart manufacturing systems (SMS) is the utilization of time-series data, making Time-Series Classification (TSC) a critical focus area. Our study aims to bridge a gap in current research by conducting a detailed experimental evaluation of modern machine learning (ML) and deep learning (DL) algorithms tailored for TSC tasks within manufacturing and industrial settings. Initially, we identified 92 algorithms from the realms of TSC and manufacturing. We methodologically selected 36 of these algorithms as the most indicative of state-of-the-art performance. These selected algorithms were then evaluated using 22 manufacturing datasets, chosen to represent different challenges in the industry. The evaluation revealed that ResNet, DrCIF, InceptionTime, and ARSENAL are the standout algorithms, all demonstrating superior accuracy across the datasets. Additionally, the study highlights the capabilities of LSTM, BiLSTM, and TS-LSTM algorithms, which excel in processing sequential data through recurrent neural network architectures. This comprehensive testing and evaluation provide practitioners with clear insights into the effectiveness of various ML and DL models, guiding better decision-making in the application of TSC techniques in smart manufacturing.

2 - Framework and Future Trends for Industry 4.0 Technologies

Arvin Shadravan, Texas A&M University, College Station, TX, United States, Hamid R. Parsaei

In the digital age, manufacturing has undergone a profound transformation due to advancements in data capture systems, information technology, and network technologies. This global shift towards digitalization introduces challenges stemming from the rapid pace of technological evolution. Advanced manufacturing strategies, notably Industry 4.0, have emerged in response, aiming to achieve "smart manufacturing". Today, smart manufacturing emphasizes technologies such as cyber-physical systems, digital twins, cloud computing, the internet of things, and big data analytics, marking a shift from knowledge-based to data-driven processes. Despite the challenges, many companies have adopted reference architectures to guide system interoperability and structure. However, the suitability of these architectures varies based on specific use cases and lacks a comprehensive understanding of existing reference architecture. This study reviews and analyzes current reference architectures for Industry 4.0, assessing their effectiveness in supporting smart manufacturing processes. It also highlights the urgent steps needed for improvement and underscores the importance of continued investment in reference architectures to secure the future of Industry 4.0. The pervasive impact of digital technologies across various industries necessitates comprehensive digital transformations involving the revamping of organizational structures, business models, and processes. Evaluating an organization's digital maturity is crucial for crafting effective digitalization strategies tailored to specific needs, unlocking potential throughout the transformation process.

3 - The Role of Smart Services in European Mechanical Engineering Companies

Thomas Meiren, Fraunhofer IAO, Stuttgart, Germany

The mechanical engineering industry has invested heavily in digitalization in recent years. This applies not only to manufacturing, but also to its service business. In particular, new digitally-enabled services are on the rise, using the growing volume of data to create new personalized solutions for customers. Examples of such 'smart services' include condition monitoring, predictive maintenance and smart training. The results of a study of the European engineering industry will be presented at the conference. In particular, the study looked at the role that smart services currently play in the service portfolio, the digital technologies on which they are based, and how they are perceived to create value for customers. The study also analyzed the differences between small and medium-sized enterprises and large companies.

4 - Generative Manufacturing Systems Using Diffusion Models and ChatGPT

Xingyu Li, Purdue University, West Lafayette, IN, United States

In this study, we introduce Generative Manufacturing Systems (GMS) as a novel approach to effectively manage and coordinate autonomous manufacturing assets, thereby enhancing their responsiveness and flexibility to address a wide array of production objectives and human preferences. GMS envisions the seamless integration of stationary machinery, autonomous assets, and diverse human workforces within futuristic manufacturing systems. In light of the growing autonomy and mobility of assets, we propose that autonomous assets and humans can dynamically relocate and self-organize across various workstations to optimize manufacturing operations and material flows.

To address the decision complexity associated with the growing number of autonomous assets and to align with human desires, our research focuses on developing novel generative AI methods based on diffusion models and ChatGPT. These methods aim to provide specialized decision support in critical manufacturing decisions such as capacity planning, layout design, and operation scheduling, responding to human textual or voice inquiries. For example, queries such as "I require a minimum production rate of 180 parts per hour" or "I specialize in collaborating with robots in Task X" are accommodated by the proposed generative AI models, offering multiple quality decisions for human selection.

We have implemented GMS in an industrial use case for part processing. Our empirical findings demonstrate GMS's significant potential in enhancing system resilience and responsiveness to uncertainties, with decision times reduced from seconds to milliseconds. The study highlights the inherent creativity and diversity in the generated solutions by GMS, facilitating human-robot collaborations and human-centric decision-making through continuous refinement.

Topics in Integer Programming and Combinatorial Optimization 1

Invited Session

OPT: Integer and Discrete Optimization

Chair: Joseph Paat, University of British Columbia, Sauder School of Business, Vancouver, BC, Canada

Co-Chair: Luze Xu, University of California, Davis, Davis, CA, 95616, United States

1 - On the Congruency-Constrained Matroid Base

Chao Xu, University of Electronic Science and Technology of China, Chengdu, China, People's Republic of, Siyue Liu

Consider a matroid where all elements are labeled with an element in Z. We are interested in finding a base where the sum of the labels is congruent to $g \pmod{m}$. We show that this problem can be solved in $\tilde{O}(2^{4m} n r^{5/6})$ time for a matroid with n elements and rank r, when m is either the product of two primes or a prime power. The algorithm can be generalized to all moduli and, in fact, to all abelian groups if a classic additive combinatorics conjecture by Schrijver and Seymour holds true. We also discuss the optimization version of the problem.

2 - Two Relaxations of Woodall's Conjecture

Siyue Liu, Carnegie Mellon University, Pittsburgh, PA, United States, Ahmad Abdi, Gerard Cornuejols, R Ravi, Olha Silina

In a digraph, a dicut is a cut where all the arcs cross in one direction. A dijoin is a subset of arcs that intersects each dicut. It is proven that the minimum size of a dicut, say k, equals to the maximum fractional packing of dijoins. Woodall conjectured in 1976 that the maximum integral packing also equals to k. In other words, it is conjectured that the minimum size of a dicut equals to the maximum number of disjoint dijoins. We prove two relaxations of Woodall's conjecture. First, we show that Woodall's conjecture is true up to a constant factor. More precisely, there exist k/6 disjoint dijoins. Second, we show that if we relax the nonnegativity of the packing coefficients, there exists an integral packing of k dijoins.

3 - A characterization of unimodularity of hypergraphs with disjoint hyperedges

Marco Caoduro, University of British Columbia, Sauder School of Business, Vancouver, BC, Canada, Joseph Paat

We are motivated by integer linear programs (ILPs) with bounded determinants in the constraint matrix. A canonical example is the maximum stable set problem in a graph, which can be modelled as an ILP where the largest determinant is exponential in the graph's odd cycle packing number. This follows from a characterization of determinants of incidence matrices by Grossman et al. During the talk, we explore a possible extension of Grossman et al.'s characterization to hypergraphs.

4 - Extended formulations for some strictly Delta-modular IPs

Joseph Paat, University of British Columbia, Sauder School of Business, Vancouver, BC, Canada, Luze Xu, Zach Walsh

Conforti et al. give a compact extended formulation for a particular class of bimodular-constrained ILPs, namely those that model the stable set polytope of a graph with odd cycle packing number 1. We extend their techniques to design compact extended formulations for the integer hull of translated polyhedral cones whose constraint matrix is strictly Delta-modular and has rows that represent a cographic matroid. This is joint work with Zach Walsh and Luze Xu.

5 - Proximity bounds and structural properties for Δ-modular integer programming

Luze Xu, University of California, Davis, Davis, CA, United States

The maximum absolute subdeterminant of the coefficient matrix is known to be an important parameter for measuring the complexity of integer programming, where an open conjecture is whether integer programs can be solved in polynomial time when the maximum subdeterminant is fixed. We call an integer matrix Δ-modular if its maximum absolute subdeterminant is Δ. In light of this conjecture, natural questions are to understand structural properties of Δ-modular matrices and to investigate proximity bounds: how large can the distance be between an optimal vertex solution of the corresponding linear program relaxation and the closest integer optimal solution in the integer linear program?

We provide a partial list of matrices that cannot exist in a Δ-modular matrix. Using Wolsey's b-hull results, we propose a method to determine the proximity bound for a fixed matrix with parametric right hand sides and objective functions. Furthermore, by adapting an algorithm by Averkov and Schymura for classifying rank-m Δ-modular matrices up to unimodular transformation, we calculate sharp proximity bounds for small m and Δ using SageMath.

Based on joint work with Matthias Köppe, Moises Reyes Rivas, Joseph Paat, Ingo Stallknecht, and Zach Walsh.

Optimization Software Session III

Invited Session

OPT: Computational Optimization and Software

Chair: Hans Mittelmann, Arizona State University, Tempe, AZ, United States

1 - Cupdlp: a Gpu Implementation of Restarted Primal-Dual Hybrid Gradient for Linear Programming

Haihao Lu, The University of Chicago, Chicago, IL, United States, Jinwen Yang

In this paper, we provide an affirmative answer to the long-standing question: Are GPUs useful in solving linear programming? We present cuPDLP.jl, a GPU implementation of restarted primal-dual hybrid gradient (PDHG) for solving linear programming (LP). We show that this prototype implementation in Julia has comparable numerical performance on standard LP benchmark sets as Gurobi, a highly optimized implementation of the simplex and interiorpoint methods. Furthermore, we present the superior performance of cuPDLP.jl with its CPU counterpart. This demonstrates the power of using GPUs in the optimization solvers.

2 - The Sas Optimization Solvers: Recent Improvements and Future Developments

Bochuan Lyu, SAS Institute Inc., Houston, TX, United States, Philipp Christophel, Laszlo Ladanyi, Menal Guzelsoy, Amar Narisetty, Rob Pratt

In this talk we present the recent improvements to the SAS linear and mixed integer linear optimization solvers and discuss future developments. Topics include Python interfaces to SAS Optimization, automated benders decomposition, presolve improvements, and cutting plane selection.

3 - Progress on Highly Parallel Ensemble Solvers

Yuji Shinano, Zuse Institute Berlin, Berlin, Germany

The Ubiquity Generator (UG) Framework was initially developed to parallelize advanced branch-and-bound based solvers. With the introduction of version 1.0, UG transitioned into a high-level task parallelization framework, enabling the parallelization of a broad range of state-of-the-art solvers. This framework facilitates the integration of multiple algorithmic implementations into a parallel solver. This presentation will highlight several success stories where UG has been utilized to solve previously intractable instances of Mixed Integer Programming, Steiner Tree, Quadratic Assignment, and Quadratic Unconstrained Binary Problems, as well as to set new benchmarks for Shortest Vector Problem instances. Finally, the most recent developments in the UG Framework will be discussed.

4 - Recent Progress in the Global Optimization of Nlps and Minlps with Baron

Nikolaos Sahinidis, Georgia Institute of Technology, Atlanta, GA, United States

We review historical progress and recent developments toward the global optimization of nonlinear and mixed-integer nonlinear programming problems with BARON. We discuss relaxation construction, preprocessing, branching, and tree management techniques. In addition to widely accepted benchmarks, we present results for a large test set.

Recent Advances in First and Second Order Methods for Nonlinear Optimization

Invited Session

OPT: Nonlinear Optimization

Chair: Ya-Chi Chu, Stanford University, Stanford, CA, 94305, United States

1 - Exploiting Negative Curvature in Conjunction with Adaptive Sampling

Albert Berahas, University of Michigan, Ann Arbor, MI, United States, Raghu Bollapragada, Wanping Dong

In this talk, we present methods that exploit negative curvature for stochastic unconstrained optimization problem.

2 - Second-Order Method for Solving Monotone Variational Inequalities: An Appoximation-Based Regularized Extra-Gradient Approach

Kevin Huang, National Taiwan University, Taipei, Taiwan, Shuzhong Zhang

In this paper, we propose a general extra-gradient scheme for solving monotone variational inequalities (VI), referred to as Approximation-based Regularized Extra-gradient method (ARE). The first step of ARE solves a VI subproblem, where the associated mapping consists of two parts: an approximation mapping satisfying a p-th-order Lipschitz bound with respect to the original mapping, and the gradient mapping of a (p+1)-th-order regularization. The optimal global convergence is guaranteed for the ARE method, while a p-th-order superlinear local convergence is shown to hold if the VI is strongly monotone. With the general concept of the approximation mapping, a variety of first-order methods as well as high-order methods can be formulated as specialized instances of the ARE framework. In this talk, we specifically demonstrate a second-order example of the ARE framework for solving monotone VIs. While the subproblem in each iteration involves solving another monotone VI, we show how it can be estimated by first-order subroutines by reducing the subproblem to simpler gradient projection steps. In particular, the technique used in this reduction is exactly an application of the ARE scheme.

3 - Barrier-based second-order method for bilevel optimization

Xiaotian Jiang, University of Minnesota, Minneapolis, MN, United States, Jiaxiang Li, Shuzhong Zhang, Mingyi Hong

In this work, we propose algorithms for solving a class of Bilevel Optimization (BLO) problems, with applications in areas such as signal processing, networking, operations research, and machine learning. Specifically, we develop a novel barrier-based second-order method that transforms the inequality-constrained BLO problem into an unconstrained problem. For the reformulated problem, we compute the implicit gradient and Hessian, and develop a cubic Newton optimization scheme, which involves a single cubic Newton step and the (approximate) solution of the linearly constrained convex lower-level task at each iteration. Under certain mild assumptions, we establish non-asymptotic convergence guarantees of the proposed method to second-order stationary points. Finally, we conduct a number of experiments to demonstrate the potential of the proposed algorithm.

4 - Frank-Wolfe type algorithms for non-convex block optimization models

Casey Garner, University of Minnesota, Minneapolis, MN, United States, Shuzhong Zhang

We present new Frank-Wolfe type algorithms for several non-convex block optimization models with convergence guarantees to first-order stationary and KKT points. Our numerical experiments showcase our method outperforms ADMM when convexity is lost. Additionally, we present new notations of stationarity which inspire novel approaches for locating first-order KKT points for non-convex block optimization models.

Multi-stage Optimization under Risk Measures

Invited Session

OPT: Global Optimization

Chair: Renyuan Xu, University of Southern California, Los Angeles, CA, United States

Co-Chair: Luhao Zhang, Columbia University, New York, NY, United States

1 - Causal Distributionally Robust Optimization -- Duality and Sensitivity

Yifan Jiang, University of Oxford, Oxford, United Kingdom

We study causal distributionally robust optimization (DRO) problems in a discrete-time dynamic setting where the model uncertainty is quantified using causal optimal transport. This discrepancy fully characterizes the spatial and temporal information of stochastic processes. Our approach focuses on two fundamental aspects: duality theory and sensitivity analysis. We establish a tractable dynamic duality for general penalized DRO. Additionally, we derive an explicit formula for the distributional sensitivity of value function to model uncertainty. We extend classical results to the so-called adapted objective functions. We illustrate our theoretical results with applications such as distributionally robust version of average value-at-risk, stochastic control, and optimal stopping.

2 - Multi-Period Compliance Mean Field Game Problems

Steven Campbell, Columbia, New York, NY, United States, Yichao Chen, Sebastian Jaimungal

We introduce a mean field game framework for multi-period inventory compliance problems with endogenous price formation. Our model allows firms to bank their inventory in order to meet obligations in subsequent periods and has applications to renewable energy certificate markets where quotas may be imposed by regulators. Under suitable conditions we prove that the representative firm's problem is convex and admits a unique solution for fixed initial data. Then, using variational arguments we characterize the mean field equilibrium in terms of a temporally and spatially coupled system of MV-FBSDEs. We conclude by illustrating numerical solutions to several examples and analyzing the properties that they exhibit.

3 - Beyond Absolute Continuity: a New Class of Dynamic Risk Measures

Luhao Zhang, Columbia University, New York, NY, United States

The modern theory of risk measures copes with uncertainty by considering multiple probability measures. While it is often assumed that a reference probability measure exists, under which all relevant probability measures are absolutely continuous, there are examples where this assumption does not hold, such as certain distributional robust functionals. In this talk, we introduce a novel class of dynamic risk measures that do not rely on this assumption. We will discuss its convexity, coherence, and time consistency properties.

4 - Optimal Sequential Hypothesis Testing with Costly Information Acquisition

Haotian Zong, Johns Hopkins University, Baltimore, MD, United States, Renyuan Xu, Luhao Zhang

We study the sequential testing problem of two alternative hypotheses regarding an unknown parameter when the information is costly. Mathematically, we frame it as a sequential optimal stopping problem with two different informational regimes. This model not only enhances the understanding of the dynamics between cost and information in hypothesis testing but also offers practical insights for adaptive and non-adaptive testing frameworks.

5 - Risk-sensitive Markov Decision Process and Learning under General Utility Functions

Zhengqi Wu, University of Southern California, Los Angeles, CA, United States, Renyuan Xu

Reinforcement Learning (RL) has gained substantial attention across diverse application domains and theoretical investigations. Existing literature on RL theory largely focuses on risk-
neutral settings where the decision-maker learns to maximize the expected cumulative reward. However, in practical scenarios, decision-makers often persist in heterogeneous risk preferences subject to outcome uncertainties, which can not be well-captured by the risk-neural framework. Incorporating these preferences can be approached through utility theory, yet the development of risk-sensitive RL under general utility functions remains an open question for theoretical exploration.

In this talk, we consider a scenario where the decision-maker seeks to optimize a general utility function of the cumulative reward in the framework of a Markov decision process (MDP). To facilitate the Dynamic Programming Principle and Bellman equation, we enlarge the state space with an additional dimension that accounts for the cumulative reward. We propose a discretized approximation scheme to the MDP under enlarged state space, which is tractable and key for algorithmic design. We then propose a modified value iteration algorithm that employs an epsilon-covering over the space of cumulative reward. In the case with access to a simulator, we demonstrate that our algorithm can efficiently identify a near-optimal policy with a sample complexity guarantee. In the case without an accessible simulator, our algorithm utilizes an upper-confidence-bound type of exploration approach, achieving a regret guarantee. For both of the algorithms, we match the theoretical lower bounds for the risk-neutral setting in terms of the total number of time steps.

Recent Advance in Optimization Under Uncertainty: Theory and Applications

Invited Session

OPT: Optimization Under Uncertainty

Chair: Man Yiu Tsang, Lehigh University, Bethlehem, PA, United States

Co-Chair: Karmel Shehadeh, Lehigh University, Bethlehem, PA, United States

1 - Distributionally Robust Hydrogen Network Expansion Planning with Decision-Dependent Uncertainty

Beste Basciftci, Tippie College of Business, University of Iowa, Iowa City, IA, United States, Sezen Ece Kayacik, Albert Schrotenboer, Ms I F A Vis, Evrim Ursavas

The transition to a green hydrogen economy faces a critical challenge known as the 'chicken-and-egg dilemma,' wherein establishing a hydrogen supply network relies on demand, while demand only grows with reliable supply. In addition, as the hydrogen market is in the early stage, predicting demand distributions is challenging. This study addresses these complex issues through the introduction of a distributionally robust decision-dependent hydrogen network expansion planning problem. The problem determines optimal locations and production capacities of the suppliers considering the moments of the stochastic hydrogen demand as a function of these investment decisions. We provide two different reformulations that consider continuous and discrete support sets. To efficiently solve the reformulations, we develop a tailored algorithm based on column-and-constraint generation. We enhance the computational performance through solving master problems to a relative optimality gap, decomposing the subproblems and heuristic warm-start cuts. Comparative experiments demonstrate the superiority of our algorithm over the classical column-and-constraint generation algorithm and Benders decomposition. To validate the effectiveness of our approach in decision-making, we create a case study focusing on the Hydrogen Energy Applications in Valley Environments for Northern Netherlands. In turn, we provide insights to policymakers for strategic development of hydrogen network, overcoming the 'chicken-and-egg dilemma' and uncertain hydrogen market conditions.

2 - Data-Driven Multistage Stochastic Optimization on TIME Series

Rohit Kannan, Virginia Tech, Blacksburg, VA, United States, Nam Ho-Nguyen, Jim Luedtke

We study a data-driven framework for multistage stochastic optimization assuming only access to a single historical trajectory of the underlying stochastic process. Conditional on the most recent observations of the stochastic process, the goal is to determine a decision policy that minimizes the expected cost over the next T time periods. We investigate a data-driven approximation in which a time-series model is fit based on the historical data, and then the residuals from this fit are used to build a discrete approximation of the stochastic process. Our formulations are flexible and can accommodate nonlinear VARX and multivariate GARCH models, and the approximation we study can be solved via the stochastic dual dynamic programming algorithm. We derive conditions on the underlying stochastic process, the time series model, and the optimization model under which solutions to the approximation possess asymptotic and finite sample guarantees. Experiments on a hydrothermal scheduling model illustrate the potential benefits of our data-driven formulations even when the time series model is misspecified.

3 - On the Trade-off Between Distributional Belief and Ambiguity: Conservatism, Bias, and Asymptotic Properties

Man Yiu Tsang, Lehigh University, Bethlehem, PA, United States, Karmel Shehadeh

We present a new data-driven trade-off (TRO) approach for modeling uncertainty that serves as a middle ground between the optimistic approach, which adopts a distributional belief, and the pessimistic distributionally robust optimization approach, which hedges against distributional ambiguity. We equip the TRO model with a TRO ambiguity set characterized by a size parameter controlling the level of optimism and a shape parameter representing distributional ambiguity. We first show that constructing the TRO ambiguity set using a general star-shaped shape parameter with the empirical distribution as its star center is necessary and sufficient to guarantee the hierarchical structure of the sequence of TRO ambiguity sets. Then, we analyze the properties of the TRO model, including quantifying conservatism, quantifying bias, and establishing asymptotic properties. Specifically, we show that the TRO model could generate a spectrum of decisions, ranging from optimistic to conservative decisions. Additionally, we show that it could produce an unbiased estimator of the true optimal value. Furthermore, we establish the almost-sure convergence of the optimal value and the set of optimal solutions of the TRO model to their true counterparts. We exemplify our theoretical results using stylized optimization problems.

4 - Distributionally Robust Optimization with Multimodal Decision-Dependent Ambiguity Sets

Xian Yu, The Ohio State University, Columbus, OH, United States, Beste Basciftci

We consider a two-stage distributionally robust optimization (DRO) model with multimodal uncertainty, where both the mode probabilities and uncertainty distributions could be affected by the first-stage decisions. To address this setting, we propose a generic framework by introducing a φ-divergence based ambiguity set to characterize the decision-dependent mode probabilities and further consider both moment-based and Wasserstein distance-based ambiguity sets to characterize the uncertainty distribution under each mode. We identify two special φ-divergence examples (variation distance and chi-square-distance) and provide specific forms of decision dependence relationships under which we can derive tractable reformulations. Furthermore, we investigate the benefits of considering multimodality in a DRO model compared to a single-modal counterpart through an analytical analysis.
We provide a computational study over the facility location problem to illustrate our results, which demonstrate that omission of multimodality and decision-dependent uncertainties within DRO frameworks result in inadequately performing solutions with worse in-sample and out-of-sample performances under various settings.

Summit - 425

Data-driven Approaches in Reliability Analysis

Contributed Session

Chair: Ziyu Wang, N/A

1 - Feature Extraction to Enhance Fault Detection in Electro-Mechanical Systems Accounting for Component Degradation

Hyunsik Yoon, Pohang University of Science and Technology, Pohang, Korea, Republic of, Duck Young Kim

Many preprocessing techniques for fault detection in electro-mechanical systems have been studied to pre-analyze different types of data collected from various sensors. Among these, feature extraction techniques from large and complex data are essential to reduce dimensionality and improve model performance. For example, Principal Component Analysis (PCA), Multi-Dimensional Scaling (MDS), Linear Discriminant Analysis (LDA), and Neural-Network (NN) based feature extraction methods have been effectively used to provide basis information about certain data characteristics such as covariance, data frequency, entropy, and labels. This paper presents a novel feature extraction method for fault detection in electro-mechanical systems in cases where degradation information is available. To do this, a multi-modal classification model integrating time series and discrete sensor data is developed to discern system degradation levels. The effectiveness of the proposed feature extraction method for fault detection is demonstrated through two case studies: an injection molding system and a bearing-shaft system.

2 - Optimal control of failing systems under deteriorating measurements

Bin Liu, University of Strathclyde, Glasgow, United Kingdom, Guo Shi, Lesley Walls

Condition-based maintenance (CBM) employs sensors and communication systems to monitor equipment conditions and present system failures based on the measurements. In CBM literature, it is often assumed that sensor readings are either perfect or only subject to measurement errors. However, this overlooks the fact that sensors, being electromechanical systems, are also prone to degradation over time due to environmental and aging factors. This degradation can compromise the accuracy of the measurements and pose challenges for maintenance scheduling. To address these challenges, we propose a three-layer factorial hidden Markov model (HMM) designed to understand the dynamics of hidden states—specifically sensor degradation, system degradation, and the translation from these hidden states to observable data. Unlike traditional HMMs, which typically utilize a complex $K^2 \times K^2$ transition matrix (K is the number of states), our model simplifies this structure into two distinct K×K matrices, significantly reducing computational demands. Additionally, we have developed an enhanced expectation–maximization algorithm to iteratively refine the model parameters based on historical monitoring data. Subsequently, we formulate the maintenance problem into a partially observed Markov Decision Process over an indefinite horizon. This optimal maintenance strategy is characterized by a control limit policy that is defined by a specific belief threshold. The effectiveness of the proposed approach is validated through numerical examples and a practical case study. This model not only improves maintenance efficiency but also enhances the reliability of the monitoring system by accounting for sensor health in the maintenance scheduling process.

3 - Condition-Based Maintenance for Degradation Systems with Quality Characteristics

Ziyu Wang, Tianjin University, Tianjin, China, People's Republic of, Xiujie Zhao

With the development of surveillance technology, especially the improvement of sensors, condition-based maintenance (CBM) has gained an increasingly popularity. However, the growing flexibility of manufacturing systems poses challenges for the accurate assessment of system states, which makes it difficult for traditional CBM to leverage its advantages. The paper investigates the optimal maintenance strategy for manufacturing systems with the consideration of state assessment uncertainties. The system consists of the production part and the output part, such as machines and products. The underlying states of machines cannot be observed directly, but can be revealed through the information of product quality. Inspections are carried out in batches and the results are used for the assessment of the underlying state of machines. The optimization model is formulated as Partially Observable Markov Process (POMDP) with the optimal maintenance policy obtained by minimizing the expected maintenance cost in both finite and infinite horizons. Point Based Value Iteration (PBVI) algorithm is used to solve the POMDP problem and to compute the expected maintenance cost. Finally, we give numerical examples to illustrate the effectiveness of the proposed model and conduct sensitivity analyses to explore the impact of parameters on the model.

Summit - 427

Data Mining Society (DMS)

Invited Session

Data Mining

Chair: Ke Yang, UNIVERSITY OF ARKANSAS AT FAYETTEVILLE, Fayetteville, 72701, United States

1 - Deep Learning Applied to Facility Inspection and Health Monitoring Using Images Captured by Uav

Ke Yang, University of Arkansas, Fayetteville, AR, United States

Maintaining sustainable, livable cities for economic growth is one of the biggest urban challenges. As part of the related efforts, it is desired to quickly detect and fix leaks in roofs that cover a large portion of building areas. However, due to the limitations of traditional inspection technologies, roof leakage caused by materials deterioration is hard to detect until leaks with various shapes, sizes, and propagation directions become visible. To overcome this practical challenge, we proposed a novel MAE-YOLOv8 model to recognize percolation features from images data captured by Unmanned Aerial Vehicles (UAVs). Specifically, the attention mechanism is embedded in a deep neural network to focus on subtle features and enhance the extraction performance in the backbone. Meanwhile, more connections are established in the neural network architecture by convolution and concatenation operations to acquire comprehensive information from the input data. Finally, the fused features are fed into the detectors for subject detection. The proposed model enables cost-effective roof leakage detection using UAV imagery. A case study including both extensive and ablation experiments demonstrates the model's performance with respect to detection accuracy and robustness. For practitioners, the model not only provides a proactive approach to urban resiliency but also promotes applications of computer vision in broader areas.

2 - A Mixture of Decomposition-based Transformer Experts Network

Yu Jin, University at Buffalo, Buffalo, NY, United States

Time series forecasting plays a crucial role in decision-making, control, and monitoring across various fields. However, accurately predicting nonstationary time series remains a challenge because traditional methods struggle to capture the complex temporal dynamics. Recent research into Transformer models for time series forecasting has showcased their ability to manage long-term dependencies. In this study, a Mixture of Decomposition Transformers Experts Network (MixDecformer) is introduced to combine the Transformer architecture with a decomposition method to capture varying levels of detail in the decomposition components and mitigate the "end effect" problem often associated with decomposition methods.

3 - Predictive Study on the Cutting Energy Efficiency of Dredgers Based on Cutting Specific Energy

JUNLANG YUAN, Wuhan University of Technology, Wuhan, China, People's Republic of, Shidong Fan, Ke Yang

Abstract: The cutter suction dredger (CSD) serves as a crucial tool in port and waterway construction. The cutter, an essential component of the CSD, directly impacts the construction progress, safety, and economic benefits. The cutting specific energy of the cutter represents the energy expended to cut rock per unit volume and is closely related to the cutter's rock breaking efficiency. This study establishes a computational model for the cutting specific energy of the cutter; based on actual engineering construction data, it introduces a method for predicting the cutting specific energy of the cutter using neural network algorithms and verifies the method through engineering examples.

Sustainable Operations in Urban Logistics

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Lei Zhao, Tsinghua University, Beijing, N/A

Co-Chair: Shu Zhang, Chongqing University, Chongqing

1 - Assessing the Effect of Consolidation of Freight Transport: A Case Study in Norway

Julio Goez, NHH Norwegian School of Economics, Bergen, Norway, Cosku Can Orhan, Mario Guajardo, Stein Wallace

The growing urban population and increasing e-commerce sales cause more and more parcel deliveries within cities. Motivated by these trends, in this project we cooperate with public authorities of a city in Norway to study the effect of consolidation of freight transportation. The effect is measured along metrics on distance and number of stops. To compute these metrics, we deploy a three-stage methodology, which involves clustering, capacitated vehicle routing, and split delivery problems. We use data on road network and population from the public authority, and on deliveries from a major carrier. We present results for a number of data instances, varying the number of companies, their size and the degree of consolidation. Ultimately, our work aims at providing city authorities with a tool for the assessment of freight transport regulations.

2 - From Resisting Algorithm to Feeding Algorithm: Strategic Behavior of Couriers

Chen Wang, Tsinghua University, Beijing, China, People's Republic of, Junjie Xiong, Lei Zhao, Jan Fransoo

This study investigates the mechanisms behind couriers' resistance and feeding behaviors under the algorithmic control of online platforms. Utilizing grounded theory and focused semi-structured interviews, we detail how couriers interpret, resist, and occasionally manipulate algorithmic controls. Our analysis aims to reveal the specific mechanisms that give rise to the ubiquitous resistance behaviors. We demonstrate how resistance transitions into "feeding" the algorithm with intentional responses and data for favorable job assignments and compensation. Based on these understandings, we propose integrating a well-being payoff into the algorithm objective, which shifts from enforcing compliance to aligning expectations and enhancing couriers' person-environment fit.

3 - Urban Delivery with Hierarchical Warehouses

Tirui Cao, Tsinghua University, Beijing, China, People's Republic of, Xue Luo, Yilei Wan, Hengle Qin, Chen Wang, Lei Zhao

To fulfill orders with various delivery urgency levels, a business-to-customer (B2C) e-commerce company employs a hierarchical warehouse logistics system, with a city distribution center (CDC) located in the suburban area and several (much) smaller forward warehouses located in the city area. The CDC is further from the last-mile stations (and requires longer delivery time) but normally has adequate inventory, whereas the forward warehouses are closer to the last-mile stations (and require shorter delivery time) but are restrained to limited inventory. In this paper, we study the daily delivery routing problem of this logistics system's first-tier transportation (i.e., the CDC or forward warehouses to the last-mile stations). We formulate this problem as a binary integer program and develop a branch-price-and-cut (BPC) algorithm, which consists of an efficient label-setting pricing algorithm and a tailored branching scheme. A comprehensive numerical study demonstrates the effectiveness of the proposed BPC algorithm and provides insights into the value of utilizing hierarchical warehouses in urban delivery.

4 - Impact of Congestion Pricing Schemes on Depot Location for Last-mile Delivery

Rui Liu, School of Economics and Business Administration, Chongqing University, Chongqing, China, People's Republic of, Shu Zhang, Ann Campbell

As urbanization increases, municipalities are concerned about traffic congestion and air pollution caused by road-based transportation. To reduce congestion and pollution in city centers, several cities have introduced congestion charging schemes to discourage vehicles from entering the inner city. The list includes London, Stockholm, Milan, Gothenburg, Valletta (Malta), Durham, Singapore, and New York City (to be started on June 30, 2024). The charging types include per-day, per-entry, per-gantry, and per-minute fees. As far as we are aware, little research has been done to examine the impact of congestion charges on logistics operations. In this study, we investigate how different charging schemes will impact the depot location in a last-mile delivery problem. We consider different geographies and identify conditions under which optimal routes with the candidate depot can be obtained in polynomial time. We find out that the congestion pricing schemes can shift the choice of depot location. That is, with different congestion charge types and rates, the optimal depot location may vary from inside the congestion zone to outside the zone, or from near the customers to far away from the customers. We propose a heuristic algorithm to find good quality depot locations for large-size problems considering different congestion pricing schemes.

5 - Learning for multiple purposes: A Q-learning enhanced hybrid metaheuristic for parallel drone scheduling traveling salesman problem

Ping Chen, Nankai University, Tianjin, China, People's Republic of, Qianlong Wang

In recent years, the integration of artificial intelligence (AI) techniques with traditional operations research (OR) methods has emerged as a significant trend for addressing combinatorial optimization problems. This paper presents a novel hybrid heuristic approach, Q-learning aided Slack Induction by String Removals (QSISRs), which combines reinforcement learning with a ruin-and-recreate metaheuristic to enhance algorithmic performance. The focus of our study is on the Parallel Drone Scheduling Traveling Salesman Problem (PDSTSP), a contemporary challenge in urban logistics distribution where drones are increasingly being utilized alongside traditional truck and courier services for last-mile delivery. The PDSTSP is characterized by a scenario where a portion of customers (ranging from 20% to 100%) are within the flight range of drones, enabling direct service from a central depot without the need for synchronization with truck operations. To evaluate the efficacy of the QSISRs, we applied it to the PDSTSP and conducted a series of numerical experiments. The results not only validate the positive impact of incorporating Q-learning into the metaheuristic framework but also demonstrate the robustness of QSISRs in effectively solving the PDSTSP. Furthermore, comparative analysis with existing heuristic approaches underscores the superiority of QSISRs, positioning it as one of the state-of-the-art methods for tackling this complex problem in the field of urban logistics.

Advancements in Marine Shipping Operations

Contributed Session

Chair: Jianxia Liu, Harbin Engineering University

1 - Decision Support for Zero-Impact Marine Shipping

Simone Philpot, University of British Columbia, Vancouver, BC, Canada, Zixuan Liu, Hugo Ricart, Clara Kaufmann, Terre Satterfield, Amanda Giang

Marine shipping enables trade, mobility, food security, emergency services, and national security. While marine vessels are the most efficient commercial transport option available in terms of CO2 emissions per cargo tonne/mile, their environmental impacts are significant. Viable and sustainable marine shipping, from both social and ecological perspectives, is an essential sustainability goal. Many technologies for reducing vessels' environmental impacts are available and in development, each with distinct trade-offs, risks, and uncertainties. Collaborating with Clear Seas, a non-profit organization, and National Research Council Canada (NRCC), we are developing decision support for evaluating vessel technologies that capture trade-offs and co-benefits across a suite of socio-environmental impacts. Here, we present findings from case studies with the Canadian Coast Guard and the NRCC. Combining expert interviews from government, industry, and consulting, with structured decision-making workshops, we identify key constraints, objectives and performance indicators around design, procurement, and research and development. For example, we find that opportunities to innovate are unevenly distributed between commercial vessels and those providing critical services, such as ferries and ice breakers. We also document challenges associated with alternative technologies around crew safety and possible new training requirements. These types of considerations impact technology feasibility and the incentives needed to support innovation. We integrate these types of elicited perspectives into an evaluative framework capturing co-benefits and trade-offs of technologies as their impacts cascade through social and ecological systems. This work contributes to a growing role for decision support as the marine shipping sector navigates changing regulatory demands and evolving technological opportunities.

2 - A Hybrid ARIMA-LSTM Approach for Improved Forecasting of Marine Bunker Prices

Orestis Schinas, University of Aegean, Athens, Greece, Theano Krassa

In the face of the maritime industry's transition towards sustainability, precise forecasting of bunker fuel prices is crucial. This study addresses a significant gap in existing forecasting methodologies for maritime fuels, a sector that has lagged in adopting advanced predictive analytics. Our research is motivated by the urgent need for more accurate forecasting methods, pivotal for managing fuel costs amid global efforts to green the shipping sector.

Based on a relevant research paper, building on the 2015 WMU study by Stefanakos and Schinas (Stefanakos & Schinas, 2015), which applied fuzzy time series to bunker price forecasting, this paper introduces a novel hybrid model that combines AutoRegressive Integrated Moving Average (ARIMA) with Long Short-Term Memory (LSTM) networks. Our model significantly improves the prediction accuracy for various types of bunker fuels—High Sulfur Fuel Oil (HSFO), Very Low Sulfur Fuel Oil (VLSFO), Marine Diesel Oil (MDO), and Marine Gas Oil (MGO)—in major ports such as Rotterdam, Fujairah, Singapore, and Houston. Importantly, this study pioneers the integration of fuzzy logic and LSTM in forecasting prices for Liquefied Natural Gas (LNG).

The methodology focuses on the statistical properties of time series, enhancing forecasting precision and enabling better strategic planning for shipping companies. This research not only advances academic knowledge but also equips the maritime industry with practical tools for navigating the sustainability transition.

3 - Time-Band Network Based Vessel Schedule Recovery in Liner Shipping Services Under Sulfur Emission Regulation

Jianxia Liu, Harbin Engineering University, Harbin, China, People's Republic of, Yuzhen Hu

To reduce sulfur emissions from ships, the International Maritime Organization (IMO) has established sulfur emission control areas (SECA), which affect liner ships in operation. Improving resilience after disruptions in operation while complying with SECA regulations is challenging for liner shipping. Therefore, this paper proposes a multi-arc reduced time-band network model for the operational vessel schedule recovery problem in liner shipping services, jointly minimizing navigation and disruption recovery costs following sulfur emission regulations. Besides, a marking method and two arc-reduced strategies are adopted in this study to improve the performance of the time-band network model, with corresponding theorem analysis. Computational experiments based on an actual liner shipping route demonstrate the effectiveness of the proposed network model, marking method, and arc-reduced strategies. This study's experimental results and management insights can provide decision-making references for the liner shipping industry, enhancing maritime transportation resilience under environmental requirements.

Summit - 430

Resilience in Aviation

Contributed Session

Aviation Applications

Chair: Felipe Delgado, N/A

1 - Navigating Turbulence: Optimizing Crew and Financial Resilience by Considering Disruptive Events

Burak Cankaya, Embry Riddle Aeronautical University, Daytona Beach, FL, FL, United States, Burak Cankaya, Eyyub Kibis, Bulent Erenay, Aaron Glassman, Ozlem Cosgun

The airline industry, known for its susceptibility to volatility, faces the continuous challenge of balancing long-term planning with the agility to respond to disruptive events. These disruptions demand a reassessment of network and fleet strategies, pilot hiring, and career progression plans, aiming for a harmony that benefits the airline and its pilots. This presentation delves into a mathematical model designed to optimize pilot resource allocation during disrupted routine operations. We'll unveil a systematic approach to pilot manpower planning, ensuring airlines are prepared to reallocate pilots among unforeseen changes efficiently. The talk will further explore a financial simulation that scrutinizes four distinct pilot allocation strategies, salary adjustments, and lay-off scenarios, assessing their viability and impact on the airline's financial health. Concluding with actionable insights, the study presents valuable case studies and recommendations for industry stakeholders, emphasizing strategies for reducing uncertainties in pilot planning. Moreover, it suggests avenues for future research to strengthen the airline's financial recovery post-disruption, ultimately fostering a more resilient airline industry.

2 - Improved Airline Network Topologies for Robust Aviation Infrastructures

Ashwini Ravindran, Texas A&M University, College Station, TX, United States, Sergiy Butenko

We propose new heuristic models for an optimal airline network design which can provide cost-efficient strategies for boosting operational efficiency and enhanced network connectivity, while also strengthening resilience against disruptions at key nodes. These newly developed theoretically optimal network designs are then compared with the existing airline networks to evaluate its performance with regard to robustness and tolerance to targeted attacks.

3 - Aircraft Maintenance Scheduling Under Uncertain Task Processing TIME

Felipe Delgado, Pontificia Universidad Católica de Chile, Santiago, Chile, Matías Villafranca, Mathias Klapp

Delays in aircraft maintenance tasks can lead to costly disruptions in airline operations, causing flight delays and significantly impacting operational efficiency and expenses. This study addresses the challenge of uncertainty in maintenance task processing times and designs cost-efficient aircraft maintenance schedules via two-stage stochastic programming. In the first stage, we determine the daily tasks to execute in each aircraft, specifying their start time and assigned maintenance base and technician. In the second stage, adjustments are made to task start times and flight departure times based on realized task processing times. The objective is to minimize costs associated with outsourced maintenance tasks, technician overtime, and flight delays. To tackle this problem, an ad-hoc Adaptive Iterated Local Search heuristic is developed, which efficiently evaluates second-stage costs while exploring first-stage solutions. The proposed approach is tested using computationally simulated instances. Results indicate significant cost savings compared to deterministic and conservative approaches, with average savings of 77% and 45%, respectively. Additionally, the proposed model outperforms a benchmark solution that optimizes time buffers by achieving 12% average cost savings. Furthermore, the study investigates the cost implications of varying structural parameters such as task granularity, processing time variability, workload, and cost structure.

Railway Freight Operations and Network Management Optimization and Modelling

Invited Session

Railway Applications

Chair: Tyler Dick, University of Texas at Austin, Austin, TX, United States

1 - Causal Inference Study on the Impact of Distributed Power on Derailment Severity

Xinhao Liu, University of Illinois at Urbana-Champaign, Champaign, IL, United States, Chen-Yu Lin, Christopher Barkan

Train derailment characteristics have been extensively analyzed. In existing studies, few of them pay attention to distributed power (DP) trains. DP trains, which can handle heavier tonnages and operate on challenging routes, have become increasingly prevalent in the U.S. over the past 15 years. This research contrasts the derailment risks associated with DP and conventional (non-distributed power) freight trains, aiming to enhance industry understanding of DP train operations.

This paper presents an exploratory and statistical analysis on the effects of DP on freight train derailments, focusing on Class I mainline and siding derailments from 2014 to 2023 across North America. We examine derailments of unit and manifest trains with and without DP, analyzing derailment characteristics, frequencies, and severities. Regression models quantify relationships, and the most frequent and severe causes of derailments for each train group are discussed.

Preliminary results indicate that DP trains, predominantly unit trains, exhibit higher derailment speeds, longer train lengths, and heavier weights compared to their non-DP counterparts, although the difference in the percentage of vehicles derailed is not statistically significant. This analysis provides insights into the safety profiles of DP trains relative to conventional freight trains.

Additionally, I aim to conduct a causal inference analysis on the impact of distributed power on derailment severity using regression methods and propensity score matching. While results are pending, this forthcoming analysis will further elucidate the causal relationships and support more advanced risk management strategies for freight train operations.

2 - Route and Schedule Optimization Method of the Mixed Train with “Empty-Loaded-Train” Service Network

Zhicong Yuan, Beijing Jiaotong University, Beijing, China, People's Republic of, Haiying Li, Ying Wang, Jiarui Zhang, Chao Yu

This study centers on a specific type of mixed train, which enables loaded wagons and empty wagons to be grouped together. To effectively organize loaded wagons and distribute empty wagons, we propose a method for optimizing the route and schedule of the mixed train. Firstly, the qualitative analysis of the train operation process in China Railway Special Cargo Logistics Co., Ltd (CRSCL) is conducted. And we propose the feasibility and potential benefit of the train. Secondly, we design a three-layer "Empty-Loaded-Train" time-space network to describe the empty wagon distribution, the loaded wagon transportation, and the train organization. Then, a multi-commodity flow model is proposed to optimize the route and schedule of the train for realizing the potential benefit. Furthermore, a sensitivity analysis is conducted in the scene of CRSCL. The results demonstrate that the delivery time of loaded wagons is shortened by 39.56% and an additional 44.44% of empty wagons distribution task is completed.

3 - Aggregated Fundamental Diagrams for Rail Traffic Flow

Han Zheng, Arizona State University, Tempe, AZ, United States, Francesco Corman, Tyler Dick, Xuesong Zhou

This presentation presents a new approach to better characterize rail traffic stream properties by connecting the concepts of Aggregated Fundamental Diagram for considering Corridor-level spatial Heterogeneity (AFD-cv) and Traffic Stream Model for homogeneous rail segments (TSM-h). Its aim is to extend the application of traffic stream models to rail traffic flows, thus bridging the gap between existing traffic flow theories and emerging rail-oriented multi-resolution modeling. Key rail-specific elements, such as block signal controls, nominal maximum speed, and intermediate station stopping plans, are considered in the proposed simplified models, by a few, crucial parameters. The TSM-h model links segment-level throughput with important variables and can recognize different rail traffic state regimes by critical points with structural mathematical equations. Based on TSM-h, the AFD-cv model introduces a train density variation index, which can reflect the effects of service stopping plans or timetables on throughput of the corridor-level system. Subsequently, a microscopic train-following model is derived from the TSM-h model, by leveraging its differentiable and continuous properties. Numerical experiments demonstrated the models' ability to represent traffic flow dynamics consistently across microscopic-to-aggregated and segment-to-corridor resolutions. The proposed models represent a step towards a better characterization of rail traffic flows and offer significant potential for planning and operational improvements.

4 - Empowering Private Rail Freight Operators: Leveraging Data-Driven Predictive Analytics

GAURAV KUMAR, University of British Columbia, Vancouver, BC, Canada, Vancouver, BC, Canada

Rail freight plays a pivotal role in fostering economic growth through its efficient services within supply chains. However, challenges such as single-track sections, manual dispatching, operational fluctuations, accidents, and diverse train characteristics often lead to delays, emphasizing the critical need for accurate Estimated Time of Arrival (ETA) predictions. To address this challenge, our study employs machine learning techniques to develop a data-driven predictive model tailored for private rail freight operators. Specifically, we utilize ensemble modeling, combining multiple linear regression and K-Nearest Neighbor algorithms, trained and validated using data collected from the Indian rail freight operator RFOY between August 2022 and October 2023. Continuously updating our estimates along the journey, we refine predictions of final destination arrival times by gathering data at specific points. Our regression model demonstrates satisfactory performance, exhibiting a strong correlation between predicted and actual arrival times, with over 95% accuracy for the majority of trips. Furthermore, we have optimized RFOY's daily operations by developing an open-source Graphical User Interface dashboard, "RFOY ETA PREDICTOR," which aligns with operational needs, ensuring efficiency throughout the rail system. Managerial recommendations encompass aligning freight train services with revenue goals, optimizing turnaround times, and boosting ETA predictions to enhance operator efficiency and customer satisfaction. These measures aim to secure a competitive edge and readiness for future demand in real-world scenarios.

Behavioral Decision-Making in Retail Operations

Invited Session

Behavioral Operations Management

Chair: Han Oh, Tilburg University, Tilburg, Netherlands

1 - Newsvendor Double-Counting Bias in Automatic Grocery Retail Replenishment

Bengü Nur Özdemir, IE Business School, Madrid, Spain, Antti Tenhiälä

This paper investigates why store managers of a supermarket chain order more than their automatic store replenishment (ASR) system's order proposals in inventory replenishment decisions. We empirically show that store managers are susceptible to a novel bias when increasing ASR orders before finalizing the replenishment decisions: newsvendor double-counting bias. This bias suggests that decision makers may apply the newsvendor logic mentally when they encounter an algorithmic proposal as if this proposal refers to a demand forecast. Yet, in the context of the usage of ASR systems, this would be a double-counting bias because the newsvendor optimization logic is applied to forecasts by the algorithm before those forecasts are converted into order proposals. We analyze ordering decisions of store managers of our collaborator supermarket chain by a probit model with sample selection model, a Heckman selection model, and an endogenous treatment regression model. All these models include exclusion restrictions adopted from the literature to tackle the endogeneity. We also control for anchoring and supply line underweighting, and take them as benchmark biases to understand the relative significance of newsvendor double-counting bias. These analyses show that order increases triggered by newsvendor double-counting bias do not lead to additional sales. This shows that the discretionary power of the users to increase orders may lead to increased inventory holding costs and waste.

2 - Behavioral multi-lever decision-making: A study of consumer return policy, price, and inventory decisions

Han Oh, Tilburg University, Tilburg, Netherlands, Huseyn Abdulla, Rogelio Oliva

We investigate consumer return policies recognized and studied by operations management scholars as an important managerial decision in a retail environment. Our research investigates, through randomized experiments, the behavioral aspects of return policy decisions and their interaction with other common operational decisions.

3 - How to Account for Behavioral Newsvendors: The Robust Buyback Contract to Address Response Uncertainty

Christina Imdahl, Eindhoven University of Technology, Eindhoven, Netherlands, Michael Becker-Peth, Kai Hoberg

The normative (expected profit-maximizing) theory assumes that decision-makers are fully rational, but in reality, they deviate from the optimal response. In contract negotiations, contract parameters are often optimized based on the assumption of rational behavior. Deviations from rational behavior can lead to significant costs for all parties involved. To address this, we propose robust optimization to obtain contract parameters that are robust to deviations from rational behavior.
We apply this optimization approach to obtain the robustly optimal contract parameters for the buyback contract when there is limited knowledge of the buyers' responses.
We compare the robust contract to the normative contract if people behave according to known behavioral models, such as mean-anchoring, bounded rationality, or a behavioral model explicitly for the buyback contract. Additionally, we test different robust contracts in a lab experiment with actual human decision-makers. The results demonstrate that a robust contract, based on simple assumptions, can outperform the normative contract in terms of risk while not sacrificing average supply chain profit. This approach offers a practical way to set contract parameters without relying on assumptions about the distribution of responses, except for the support.

4 - Late Payments, Higher Prices? An Experimental Investigation of Competitive Procurement

Kyle Hyndman, The University of Texas at Dallas, Richardson, TX, United States, Matthew Walker

The decision to pay one's suppliers late is commonplace across global supply chains. Motivated by our direct interactions with buyer-side and supplier-side organizations and our analysis of regulatory data, we construct a game-theoretic model and investigate the strategic element to late payments using laboratory experiments. We find that the anticipation of late payments leads to higher supplier prices and lower expected buyer profits. We examine whether an economic incentive (penalty for late payment) deters buyers from reneging upon an agreed payment term. The effectiveness of introducing a penalty for late payment is not obvious, because some buyers may choose to circumvent the penalty by offering a longer payment term up front, and the penalty may influence suppliers' bidding strategies. We find that setting the highest penalty for late payment is an effective deterrent mechanism and leads to the highest expected buyer profit through its effect on supplier competition. Thus, establishing a credible commitment to pay one's suppliers on-time is a cost-efficient managerial strategy for buyers. However, a welfare loss arises if the penalty is not set high enough because it fails to align incentives for a subset of buyers.

Stochastic Models and Optimization in Service Systems: Matching, Pricing, Scaling, And Planning

Invited Session

Applied Probability Society

Chair: Sophie Yu, Stanford University, Durham, NC, United States

1 - Greedy Matching of Impatient Agents: The Role of Inventory

Angela Kohlenberg, Northwestern University, Evanston, IL, United States

We study dynamic matching in two-sided markets with heterogeneous and impatient demand and supply, and demand-dependent match rewards. These markets face a trade-off between delaying matches to allow for better options and performing matches quickly to prevent agent abandonment. A greedy matching policy attempts to match agents immediately upon their arrival. A policy that greedily matches agents over the entire market ignores the potential benefits of reserving inventory (waiting agents) for better future matches. However, greedily matching supply over a subset of the highest-reward demand may sacrifice the opportunity to match supply before it abandons.
Our results reveal that the optimality of greedy policies depends on the fundamental questions: can and should excess inventory be held on the supply-side of the market? We derive precise expressions of the market parameters, which are translated into intuitive market characteristics, to answer these questions. A policy is scale optimal if its reward loss due to abandonment is on the same order as the optimal policy. We develop an algorithm for general two-sided networks that identifies whether a greedy policy is scale optimal, and, if so, specifies the optimal market design such that greedily matching agents over specified partitions of the network is scale optimal.

2 - Distributed Tate Scaling in Large-Scale Service Systems

Debankur Mukherjee, Georgia Tech, ISyE, Atlanta, GA, United States, Daan Rutten, Martin Zubeldia

In this talk, we will consider a large-scale parallel-server system, where each server independently adjusts its processing speed in a decentralized manner. The objective is to minimize the overall cost, which comprises the average cost of maintaining the servers' processing speeds and a non-decreasing function of the tasks' sojourn times. The problem is compounded by the lack of knowledge of the task arrival rate and the absence of a centralized control or communication among the servers. We draw on ideas from stochastic approximation and present a novel rate scaling algorithm that ensures convergence of all server processing speeds to the globally asymptotically optimum value as the system size increases. Apart from the algorithm design, a key contribution of our approach lies in demonstrating how concepts from the stochastic approximation literature can be leveraged to effectively tackle learning problems in large-scale, distributed systems. En route, we will also discuss the performance of a fully heterogeneous parallel-server system, where each server has a distinct processing speed, which might be of independent interest.

3 - Electric Vehicle Fleet and Charging Infrastructure Planning

Sushil Mahavir Varma, Georgia Tech, Atlanta, GA, United States, Francisco Castro, Siva Theja Maguluri

We analyze an optimal electric vehicle (EV) fleet and charging infrastructure capacity planning problem in a spatial setting. As customer requests arrive at rate λ, the system operator must determine the minimum number of vehicles and chargers for a given service level along with a matching and charging policy that maximizes the service level. We provide a sharp characterization of the fleet size and the charging infrastructure requirements as the demand grows. While a system in which charging times are negligible needs extra $\Theta(\lambda 2/3)$ vehicles on top of the nominal capacity, we show that an EV system has a fundamentally different scaling. Due to charging times, the nominal capacity of the system is increased, but this increased capacity allows for an optimal EV dispatching policy to result in an extra fleet requirement of only $\Theta(\lambda\nu)$ for $\nu \in (1/2, 2/3]$, depending on the number of charging stations and the size of the EV battery packs. We propose the Power-of-d dispatching policy, which achieves this performance by selecting the d closest vehicles to a trip request and choosing the one with the highest battery level. We conduct detailed simulations that verify our scaling results. Lastly, we discuss how to extend our results to accommodate time-varying cyclic demand patterns.

Recent Advances in Approximate Dynamic Programming

Invited Session

Applied Probability Society

Chair: Parshan Pakiman, Chicago Booth, 5751 S Woodlawn Ave, Chicago, IL, 60637, United States

Co-Chair: Daniel Adelman, University of Chicago, Booth School of Business, Chicago, IL, United States

1 - Unit Commitment Without Commitment: Managing An Integrated Energy System Under Uncertainty

David Brown, Duke University, Durham, NC, United States, James Smith

Renewable energy sources like solar and wind are prone to variability and uncertainty. Although variable and uncertain demand has always been an issue for power systems, the growing reliance on renewable energy increases the need for system operators to manage production systems carefully. Current industry practice at these utilities involves solving ``unit commitment'' and ``economic dispatch'' optimization problems to choose production plans: these models, while complex, do not explicitly incorporate uncertainty. In this work, we develop an analytical framework based on weakly coupled stochastic dynamic programming to help system operators manage production under uncertainty. We develop relevant theory and demonstrate this dynamic framework using data from the Duke Energy Carolinas and Progress systems. Our numerical experiments demonstrate that this dynamic approach is computationally feasible at an industrial scale. Compared to current practice, our approach is computationally efficient and substantially improves operational efficiency, with the efficiency gains increasing in the renewable capacity of the system.

2 - Multi Shot Linear Programming Approximation of Average Cost Markov Decision Processes

Selva Nadarajah, University of Illinois Chicago, College of Business Administration, Chicago, IL, United States, Parshan Pakiman

Approximate linear programming is a foundational approach to obtain control policies for large-scale average cost Markov decision processes (MDPs) arising in domains such as queuing control, inventory management, and healthcare operations. Its most common use involves approximating the average cost MDP by a perturbed MDP connected to a discounted cost model and then applying approximate linear programming to the resulting perturbed MDP. In contrast, a pioneering approximate linear programming approach directly approximates the average cost MDP in two phases but has been largely overlooked because it cannot guarantee good policy performance. We revisit this pioneering approach and address its limitations by combining random features and multiple approximation attempts. We establish a convergence rate for phase one lower bound to reach the optimal policy cost with a high probability as more random features are sampled. Given a near-optimal phase one lower bound, phase two takes multiple shots at approximating the MDP bias function using a sequence of randomized linear programs that provide policies with improving worst-case performance. Linear programs in this sequence have increasing numbers of random features and are warm-started using information from the immediately preceding linear program. Numerical experiments on joint replenishment and perishable inventory control applications highlight the efficacy of the proposed approach.

3 - Measurized Discounted Markov Decision Processes

Daniel Adelman, University of Chicago, Booth School of Business, Chicago, IL, United States, Alba Olivares Nadal

We build a framework that facilitates the analysis of discounted infinite horizon Markov Decision Processes (MDPs) by visualizing them as deterministic processes where the states are probability measures on the original state space and the actions are stochastic kernels on the original action space. We provide a simple general algebraic approach to lifting any MDP to this space of measures; we call this to measurize the original stochastic MDP. We show that measurized MDPs are in fact a generalization of stochastic MDPs, thus the measurized framework can be deployed without loss of fidelity. Lifting an MDP can be convenient because the measurized framework enables constraints and value function approximations that are not easily available from the standard MDP setting. For instance, one can add restrictions or build approximations based on moments, quantiles, risk measures, etc. Moreover, since the measurized counterpart to any MDP is deterministic, the measurized optimality equations trade the complexity of dealing with the expected value function that appears in the stochastic optimality equations with a more complex state space.

Capacity Planning for Amazon Customer Service Contact Center

Invited Session

Applied Probability Society

Chair: Xin Liu, Amazon.com Services LLC, Seattle, WA, United States

1 - Prediction interval in demand forecasting

Stephanie Mao, Amazon.com, Seattle, WA, United States

While a point forecast model can provide accurate predictions, it only represents the expected value of future realizations, failing to capture demand variability or uncertainty. Such information is crucial for businesses to plan with flexibility and meet service level targets, particularly in highly volatile situations like holidays and special events in the retail industry. For Amazon, understanding future contact volatility is further significant given its large scale, which can potentially lead to huge cost savings.

In this presentation, we introduce a new approach that generates predictive percentiles and prediction intervals to complement the given point forecast of Customer Contact Demand. This approach incorporates dynamic horizon-specific modeling and error decomposition method to balance underlying model dynamics and evolving data patterns. It prepares businesses for stochastic optimization by providing a range of potential outcomes with quantified likelihood. By leveraging prediction intervals, businesses can make more informed decisions regarding staffing, hiring, and operational cost management, especially in highly volatile demand situations.

2 - Tesseract - forecasting automation solutions

Yongfeng Hui, Amazon, Seattle, WA, United States, Chen Liang

Accurate forecasts of Customer Contact Demand play a pivotal role in the strategic planning processes of Amazon Customer Service, driving decisions on resource allocation and capacity planning. However, the dynamic nature of time series data presents significant challenges in developing effective forecasting models. Customer Contact Demands are affected by various factors, including sales events, operational changes, yearly and weekly seasonalities, and holidays. Additionally, the complexity of time series increases when covering multiple business verticals, such as countries and product lines, especially for those with limited historical data. In this presentation, we introduce an end-to-end framework tailored to address the challenges of understanding time series of Customer Contact Demand. By integrating advanced analytics with user-friendly interfaces, we ensure the accessibility of actionable insights for non-expert business users. This empowers organizations to make informed decisions, drive efficiency, and enhance customer satisfaction in the ever-evolving landscape of customer service management.

3 - A doubly stochastic Poisson arrival model for Amazon contact center: Performance evaluation and staffing implications

Kevin Melendez, Amazon.com Services LLC, Seattle, WA, United States, Xin Liu

Motivated by non-Poisson stochastic variability found in Amazon CS arrival data, we extend established service system staffing algorithms using the square-root staffing formula to allow for non-Poisson arrival processes. Using a doubly stochastic model, we aim to characterize a general arrival process that is more variable than the commonly used Poisson model. We derive the heavy-traffic limit of a many-server queueing model driven by this non-Poisson arrival process and we provide simple formulas to quantify the performance impact of the non-Poisson arrivals upon the staffing decisions, in order to achieve the desired service level goal. We conduct simulation experiments to demonstrate that the staffing algorithm is effective in achieving designated service level constraints.

4 - Short-term planning in Amazon customer service

Adolfo Rocco, Amazon, Seattle, WA, United States, Kevin Melendez

This paper introduces the short-term planning (STP) process within Amazon's customer service (CS). The STP aims to efficiently plan both internal headcount capacity and outsourced capacity to meet customer demand while adhering to labor laws, operational constraints, and service level targets. Our goal is to design the STP that optimizes the shift schedules to minimize costs and maximize operational performances, while providing the best experience for both customers and customer service agents (CSAs). To achieve this, we present three optimization models: (1) schedule generation, (2) short-term forecast allocation, and (3) shift assignment. Schedule generation determines the optimal set of shifts to cover anticipated demand. Short-term forecast allocation distributes the forecasted workload through different channels across different sites and skill groups. Finally, shift assignment matches individual agents to the generated schedules based on their skills, preferences, and operational requirements. Most of the models have been deployed into production, with an adoption level of 100% in North America, 65% in Europe, and 84% in Asian pacific region. As one of the fundamental investments, the STP initiative has standardized the shift generation and assignment across all regions. For 2024, our goal is to achieve $16MM cost savings via the CSA occupancy improvement and attrition rate reduction.

5 - Estimating interval-based tail probability of delay in real time

Ling Zhang, Amazon Corporate LLC, Bellevue, WA, United States, Yunan Liu

We develop effective methodologies and algorithms to estimate the interval tail probability of delay (iTPoD) of waiting time in an interval. The iTPoD measures the fraction of all customer arrivals in an interval [0, T] experiencing a shorter-than-w waiting time, where T is the length of the time interval and w is the waiting time threshold (e.g., T = 24 hours and w = 60 seconds). Our iTPoD predictor is dubbed the finite-interval lookahead estimator (FILE). It predicts the SL in a forward-looking fashion using input parameters including the future demand forecast, future agent capacity, average handling time, average abandonment time and real-time queue information. FILE is developed using three important building blocks: the snapshot SL estimator, the many-server fluid queueing model, and the truncated Gaussian approximations. The effectiveness of FILE has been investigated and confirmed by numerical experiments and computer simulation. We have developed a python package for FILE and it is adopted by our engineer partner in production.

1 - Importance Sampling Strategy for Heavy-Tailed Systems with Catastrophe Principle

Xingyu Wang, IEMS, Northwestern University, Evanston, IL, United States, Chang-Han Rhee

Large deviations theory has a long history of providing powerful machinery for designing efficient rare-event simulation techniques. However, traditional large deviations theory fails to provide useful bounds in heavy-tailed contexts, and designing efficient rare-event simulation algorithms for heavy-tailed systems has been considered challenging. Recent developments in the theory of heavy-tailed large deviations enable the design of a strongly efficient importance sampling scheme that is universally applicable to a wide range of rare events. In this talk, we provide an overview of the recent developments in the large deviations theory for heavy-tailed stochastic processes, which is followed by an account of the design principle behind the strongly efficient importance sampling scheme for such processes. The implementations of the general principle are demonstrated through examples in different contexts, including settings where the entire path of the underlying system is computationally infeasible to simulate.

2 - US Mass Killings as Stochastic Processes: Exploring the Social Contagion Hypothesis

Zachary Hornberger, University of Illinois at Urbana-Champaign, Champaign, IL, United States, Douglas King, Sheldon Jacobson

Although mass killings in the United States are rare, these tragic events leave permanent marks on communities and evoke fear in the public. There is currently debate as to whether mass killings exhibit characteristics of social contagion. Social contagion is the phenomenon where the arrival of one event increases the likelihood of subsequent events, thus spreading behavior from person-to-person over a social network. While social contagions are frequently studied by sociologists and psychologists, operations researchers can examine the veracity of contagion claims by comparing their arrival to what would be expected from a Poisson process. When arrival data is collected in practical systems, however, it is often gathered periodically (e.g., daily, monthly, quarterly) instead of continuously due to resource or technological constraints; this is the case for available data on U.S. mass killings. Despite the prevalence of Poisson process modeling in social science, little research has explored how the periodic collection of data affects the applicability of this model. Our research studies how discretization impacts the Poisson process model's interarrival distribution and introduces the periodically-observed time-homogeneous Poisson process (PTPP) model as a viable alternative. Through the employment of the PTPP model, our findings suggest that all primary types of mass killings, when modeled as stochastic processes, behave similar to Poisson processes. This supports the conclusion that U.S. mass killings are not socially contagious.

3 - ScoreFusion: Fusing Score-based Generative Models via Kullback–Leibler Divergence Barycenters

Hao Liu, Stanford University, Stanford, CA, United States, Jose Blanchet, NIAN SI

We study the problem of fusing pre-trained (auxiliary) generative models to enhance the training of a target generative model. We propose using KL-divergence weighted barycenters as an optimal fusion mechanism, in which the barycenter weights are optimally trained to minimize a suitable loss for the target population. While computing the optimal KL-barycenter weights can be challenging, we demonstrate that this process can be efficiently executed using diffusion score training when the auxiliary generative models are also trained based on diffusion score methods. Moreover, we show that our fusion method has a dimension-free sample complexity in total variation distance provided that the auxiliary models are well fitted for their own task and the auxiliary tasks combined capture the target well. The main takeaway of our method is that if the auxiliary models are well-trained and can borrow features from each other that are present in the target, our fusion method significantly improves the training of generative models. We provide a concise computational implementation of the fusion algorithm, and validate its efficiency in the low-data regime with numerical experiments involving mixtures models and image datasets.

4 - Optimizing Input Data Collection for Ranking and Selection

Eunhye Song, Georgia Institute of Technology, Atlanta, GA, United States, Taeho Kim

We investigate a Bayesian ranking and selection (R&S) problem under input uncertainty when all solutions share a collection of independent input models. These Bayesian input models are updated as more data is collected from multiple independent sources ultimately converging to the data-generating distributions. Our goal is to design a sequential sampling algorithm that identifies the optimum under the data-generating distributions most efficiently given a data collection budget. Two types of data collections are considered: input data acquisition from each source and simulation sampling for a solution at a particular set of input models. We propose a Bayesian estimator of the optimum and characterize its probabilistic convergence rate to the optimum focusing on the case when there is a finite set of candidates for the true input distributions. We derive the optimal asymptotic static sampling ratios for the input data collection and simulation by maximizing the rate function. Based on this analysis, a sequential sampling algorithm is proposed, which is further bolstered by combining the kernel ridge regression. We benchmark our algorithm against a state-of-the-art method that consider the same R&S problem.

Payment Models in Healthcare

Invited Session

Health Applications Society

Chair: Kenan Arifoglu, UCL School of Management, University College London, London, E14 5AA, United Kingdom

1 - Promoting Collaborative Care: Relative Performance-Based Payment Models for Hospitals and Post-Acute Care Providers

Hang Ren, George Mason University, Fairfax, VA, United States, Kenan Arifoglu, Tolga Tezcan

Diagnosis-Related Group (DRG) and bundled payment models are widely used in healthcare reimbursement by entities like the Centers for Medicare & Medicaid Services (CMS) and insurance companies. However, these models were primarily designed for conditions managed by a single healthcare provider in a centralized manner, often overlooking the complexities of cases requiring post-acute care (PAC) following an initial hospital stay. This can result in inadequate incentives for effective care coordination between hospitals and PAC providers, especially when treatment decisions are decentralized.

Motivated by the Comprehensive Care for Joint Replacement (CJR) payment model recently introduced by CMS, which holds hospitals accountable for the quality and cost of the entire CJR episode, including the cost of PAC, we propose simple payment models that incentivize hospitals and PAC providers to collaboratively enhance the cost efficiency and quality of care for such conditions. Our approach extends traditional payment models by introducing performance targets for all providers, encompassing the entire care episode. Using a game-theoretical model, we demonstrate that the proposed payment model elicits socially optimal actions from all providers, under various assumptions. Importantly, our models do not require detailed knowledge of the hospital-PAC network structure but rely solely on observed cost and quality outcomes within the entire system.

Furthermore, while the CJR payment model represents a positive step forward, our analysis reveals potential areas for improvement. Specifically, we suggest that holding both hospitals and PAC providers financially accountable, instead of solely focusing on hospitals, would yield further enhancements in the care delivery model.

2 - Contracting Telemedicine: A Game-Theoretic Consideration for Nhs Advice & Guidance

Zidong Liu, University of Cambridge, Cambridge, United Kingdom, Feryal Erhun, Houyuan Jiang

In the UK, General Practitioners (GPs) serve as the primary point of contact for patients, conducting initial assessments and treatments. Specialist consultations generally require a GP referral, except in emergencies. The effectiveness of this gatekeeping role is crucial for the healthcare system's success. Nonetheless, the system is plagued by diagnostic errors, referral inefficiencies, and concerns about the sustainability of traditional outpatient services. To address these issues, the Advice & Guidance (A&G) service has been introduced as an optional telemedicine gatekeeper prior to outpatient referrals. This paper explores various incentive mechanisms to maximize the effectiveness of this telemedicine service in reducing inefficiencies. We propose a game-theoretic model to evaluate the system's performance under different regulatory and contractual frameworks. Our analysis includes scenarios with no regulation, traditional fee-for-service (FFS) contracts, and two-part tariff (TPT) contracts, all of which generally fail to align system incentives. We introduce cost-sharing performance-based (COPE) contracts that incentivize both the commissioner and the hospital towards socially optimal outcomes. Furthermore, we expand our analysis to a multi-period dynamic context, allowing GPs to learn and enhance their referral quality over time. We propose dynamic cost-sharing performance-based (Dynamic COPE) contracts as a solution for long-term system coordination.

3 - Blended Payment Scheme of Nhs England: Issues and Remedies

Sara Mohammadi, UCL School of Management, London, United Kingdom, Kenan Arifoglu, Bilal Gokpinar

The National Health Service (NHS) England has implemented the blended payment scheme, integrating elements from two previously established payment systems: block contracts and Payment by Results (PbR). Block contracts entail a prospective lump-sum payment given to hospitals for accessing a defined range of services for a particular period. On the other hand, PbR is an activity-based payment under which a hospital receives a certain payment (tariff) for each admission of a patient in each Healthcare Resource Group (HRG). Under the blended approach, hospitals receive an annual fixed payment similar to block contracts to secure an adequate supply of health care services and guarantee an initial income for hospitals. Then, the fixed payment is supplemented by a variable component to reflect differences between planned and actual levels of activity. Blended payment is developed to help hospitals make the most efficient use of available resources and remain in financial balance. Consequently, it can influence hospitals' decisions about their costs and planned activity levels which reflect their preparation levels and expected capacity to deliver the anticipated level of services. Utilizing a principal-agent model, we compare hospitals' decisions regarding their planned activity levels and costs under the three defined payment schemes with socially optimal actions. Our findings reveal that due to information asymmetry between hospitals and the NHS, none of the existing payment schemes can achieve socially optimal outcomes. Consequently, we propose a new payment model to address this issue effectively.

4 - Promoting Home Dialysis for Esrd Patients: A Comparative Study of Incentive Models

Salar Ghamat, Wilfrid Laurier University, Waterloo, ON, Canada, Maryam Afzalabadi, Mojtaba Araghi

Healthcare payers are actively seeking methods to improve the quality of life for patients with end-stage renal disease (ESRD) and decrease treatment expenditures by increasing the rate of home dialysis. In this paper, we develop a game-theoretical model to study two incentive models, namely target-based and competitive, offered by a payer to encourage two heterogeneous providers' efforts in increasing home dialysis utilization for ESRD patients. We show that the payer can achieve the first-best home dialysis rates with both incentive models by carefully choosing the performance benchmarks. Our paper is the first in the incentive payment literature to model and investigate compound incentive mechanisms, including improvement and achievement benchmarks. These benchmarks encourage diverse providers to work towards achieving the award regardless of their different characteristics. Additionally, we are the first to propose a competitive incentive mechanism between healthcare providers in the healthcare operations literature. Finally, we present a numerical analysis that feeds insights into the existing practical measures of these incentive models for the payer.

Optimization in Health Systems and Policy Planning

Invited Session

Health Applications Society

Chair: Anahita Khojandi, University of Tennessee, Knoxville, TN, United States

Co-Chair: Jeremy Watts, University of Tennessee, Knoxville, TN, United States

1 - Ai-Driven Management of Comorbid Hypertension and Diabetes for Shared Decision-Making

Jeremy Watts, University of Tennessee, Knoxville, TN, United States, Faezeh Bagheri, Nafiseh Payani, Denizhan Demirkol, Amy Cizik, Brian Sauer, Makoto Jones, P Jon White, Merry Ward, Andrew Farrell, Anuj Kapadia, Anahita Khojandi

Our goal is to provide clinicians with treatment alternatives for managing comorbid hypertension and diabetes that account for patient preferences to facilitate shared decision-making. To do so, we present Comorbid Hypertension AI-driven Management Pathways (CHAMP). CHAMP models comorbid hypertension and diabetes progression subject to interventions (medication and/or lifestyle changes) and estimates patient-specific outcomes through an autoregressive simulation model. Consequently, CHAMP determines a diverse set of equally good intervention policies using a reinforcement learning algorithm. These policies are assessed by quality-adjusted life years estimates, enabling the comparison of intervention policies based on combinations of medication classes (angiotensin receptor antagonists or angiotensin II receptor blockers, beta-blockers, calcium channel blockers, and diuretics) and/or lifestyle changes to accommodate patient preferences. We present CHAMP's performance for the MIMIC-IV database and provide insights.

2 - Reducing Overdose Deaths and Mitigating County Disparities Through Sequential Optimization of Substance use Treatment Center Locations

Matthew Baucum, Colorado State University, Fort Collins, CO, United States, Matt Harris, Larry Kessler, Guanyi Lu

Substance use disorder (SUD) is a pressing health concern in the U.S., and connecting communities with accessible SUD treatment is a growing public health imperative. We study the optimal allocation of substance use treatment centers across counties within U.S. states over a multi-year time horizon. We use a three-part objective function which minimizes (1) statewide overdose deaths, (2) mismatch between counties' treatment center access and overdose death rates ('inequity'), and (3) mismatch between counties' treatment center access and population ('inequality'). We also consider the temporal interdependence of counties' treatment center allocations and their death-rate-based 'equity' targets, which depend on such allocations. We use a predict-then-optimize approach based on data from over 2,500 U.S. counties between 1999 and 2016. We first estimate SUD treatment centers' causal impact on county-level overdose death rates, using SUD parity laws as an instrument. We then use these estimates in a nonlinear program that reallocates states' observed levels of SUD treatment funding. Results suggest that this approach can meaningfully reduce statewide overdose deaths and between-county disparities in treatment access. Prioritizing death rate reductions over equity/equality results in more resources being directed to high-population counties, where treatment centers are most effective. Prioritizing equity/equality in treatment access results in more resources being directed to under-served low-population counties. We also find that states differ in their Pareto-optimal tradeoffs between death rates and inequity/inequality. Finally, decision makers may wish to avoid increasing all counties' SUD funding by the same percentage, which can exacerbate between-county disparities in treatment access.

4 - Optimization of Statewide Trauma Systems Driven by Care Delivery Quality and Population Equity

Xiaonan Sun, University of Washington, Seattle, WA, United States, Shan Liu, Rebecca Maine

Organized trauma systems play a crucial role in reducing mortality among severely injured patients, ensuring timely access to critical care. However, despite their benefits, disparities persist, and measuring care quality remains complex. While many studies have focused on optimizing emergency transport services, care quality and equity have often been overlooked. In this research, we aim to develop a systematic framework to optimize a statewide trauma system based on care delivery quality and population equity.

We developed a systematic framework improving care quality while addressing population equity. This objective is achieved by establishing and assigning hospital profiles representing performance targets which can be used to guide resource allocation and operational adjustment decisions. Using state data, we established a set of comprehensive trauma care quality metrics for distinct population groups formed by sociodemographic factors and Injury Severity Score (ISS). We then created a quality index to represent trauma care quality accounting for hospital variations using a Principal Component Analysis (PCA) analysis of the quality metrics. Next, we created hospital profiles using quality index of each population group, which were estimated from data and imputed using a linear mixed-effects model. We formulated a mixed-integer linear program (MILP) to maximize the quality index of targeted population groups under various equity objectives. The model identified optimal hospital profile assignments as proxies for performance targets for the hospitals. These results help identify necessary resources for performance enhancement, guiding hospitals in making targeted improvements to better serve diverse patient populations.

Co-Chair: Muyan Jiang, UC Berkeley, Berkeley, CA, 94706, United States

1 - Evaluating the Efficacy of Providers' Compensation Contracts in Improving Participant Retention for Clinical Studies

Xueze Song, University of Illinois Urbana-Champaign, Urbana, IL, United States, Mili Mehrotra, Tharanga Rajapakshe

To improve participant retention, the clinical study sponsors often provide monetary payments to participants and compensate providers (investigators and coordinators) for their efforts. In this work, our goal is to examine the cost performance of three widely adopted compensation contracts—fixed (FC), linear (LC), and condition linear (CLC) in improving participant retention. To this end, we analyze a sponsor's decisions regarding monetary payments and providers' efforts under a centralized model, and identify the optimal contracts for the providers under the two decentralized team structures: (i) the sponsor-investigator (SI) model and (ii) the outsourcing (OM) model.

2 - The Effect of Process Standardization in Healthcare Operations

Anand Bhatia, UNC, Chapel Hill , NC, United States

Healthcare services provided to patients with similar health conditions are known to vary. Standardization of healthcare delivery is a relatively new, yet hotly debated approach to address clinical variations. Previous research on process standardization has focused on measuring adherence to established national protocols that are available only for a limited set of disease states. Using detailed nonpublic inpatient discharge data from about 35 million inpatient stays at 296 acute care hospitals in California between 2008-2016, we create a metric that quantifies process standardization measured in terms of consistency of healthcare services rendered. We examine the impact of such process standardization on the cost, quality, and variation in quality of care delivered by a hospital. We find that process standardization is associated with a reduction in cost per discharge, readmission rates and variation in readmission rates. We also find that increasing capacity utilization and complexity of patient disease mix is associated with a reduction in process standardization, while increasing focus and process adherence is associated with an increase in process standardization. We also find that the impact of process standardization varies across different departments and different disease states, and improves cost and quality performance in majority of cases. Finally, we show that benefits of process standardization in terms of readmission rates have diminishing marginal returns at a hospital.

3 - Optimal Contract Design for End-of-Life Care Payments

Muyan Jiang, UC Berkeley , Berkeley , CA, United States

A large fraction of total healthcare expenditure occurs due to end-of-life (EOL) care, which means it is important to study the problem of more carefully incentivizing necessary versus unnecessary EOL care because this has the potential to reduce overall healthcare spending. This paper introduces a principal-agent model that integrates a mixed payment system of fee-for-service and pay-for-performance in order to analyze whether it is possible to better align healthcare provider incentives with patient outcomes and cost-efficiency in EOL care. The primary contributions are to derive optimal contracts for EOL care payments using a principal-agent framework under three separate models for the healthcare provider, where each model considers a different level of risk tolerance for the provider. We derive these optimal contracts by converting the underlying principal-agent models from a bilevel optimization problem into a single-level optimization problem that can be analytically solved. Our results are demonstrated using a simulation where an optimal contract is used to price intracranial pressure monitoring for traumatic brain injuries.

Empirical Retail Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Diwas KC, Emory University, Atlanta, GA, United States

1 - Impact of Temporary Store Closures on Online Sales: Evidence from a Natural Experiment

Ragip Gurlek, Emory University, Atlanta, GA, United States, Diwas KC, Paolo Letizia

This paper examines the impact of retail store closures on omnichannel sales and consumer shopping behavior in the context of the COVID-19 pandemic. To explain the likelihood of store closure, we develop a novel instrumental variable motivated by varying geopolitical responses across the US to the pandemic.

Using data from a luxury fashion retailer, we find that when a store is closed, the volume of online orders originating from its location increases by 24%. Furthermore, when the retailer closes 10% of its stores, the omnichannel total sales (offline + online) decrease by 5.5%. Our findings indicate that the online channel enables the retailer to recover 11% of offline sales that would have otherwise been lost due to store closures. We also show that compared to existing e-shoppers, new e-shoppers are more likely to order popular product models in an effort to mitigate the mismatch risk associated with online transactions. For new e-shoppers, the likelihood of ordering a popular model stands at 70%, whereas it is 45% for existing online consumers. Additionally, the conservative behavior of favoring popular models reduces the likelihood of returns by new e-shoppers.

Even for luxury apparel requiring “touch and feel” and customer tryout, the option to purchase online proves immensely valuable. The tendency of new e-shoppers to limit mismatch risk by choosing popular products may create an opportunity for retailers to strategically target these inexperienced online customers with advertisements, product promotions, or virtual fitting rooms, all geared toward reducing online shopping risk of product mismatch.

2 - Inferring Consideration Sets from Heatmap Data

Zahra Ziaei, Frank Barton School of Business, Wichita, KS, United States, Chloe Glaeser, Adam Mersereau, Seyed Emadi, Vidyaranya Gargeya

Ignoring consideration sets in customer purchase models can lead to biased preference estimates, yet inferring these sets in brick-and-mortar contexts is challenging. We demonstrate that "heatmap data" from in-store sensors can address this issue. Unlike clickstream data in e-commerce, which tracks individuals, heatmap data shows aggregate customer traffic. Despite this, we show that heatmap data can replicate many benefits of individual-level data. In non-parametric models, heatmap data allows the identification of consideration sets that would not be possible with sales data alone. In parameterized models, it enables estimation without exclusion-restriction assumptions, reducing finite-sample bias. Using heatmap sensors in an apparel store, we obtain distinct coefficient estimates, improved predictive accuracy, and better revenue estimates for product placement decisions.

3 - Gender Pricing and Fairness in An Online Marketplace: Pink, Blue, OR Purple?

Xiaoyan Liu, Santa Clara University, Santa Clara, CA, United States, Diego Aparicio, Maxime Cohen, Davide Proserpio

Gender-based pricing disparity raises fairness concerns and can be detrimental to the economy and our society. In this paper, we investigate gender-based pricing disparity in Amazon, the major online e-commerce platform by leveraging a large dataset from Amazon.com in the year 2023. Our data set encompasses approximately 16.5 million item-price records across a wide array of product categories. We find evidence of blue tax as well as pink tax across different product categories. We also show evidence of disproportional discount patterns based on targeted genders.

4 - Green E-Commerce: Environmental Impact of Fast Delivery

Chenshan Hu, Washington University in St. Louis, Saint Louis, MO, United States, Xiaoyang Long, Jiankun Sun, Dennis Zhang

It is well-established that faster delivery in e-commerce increases consumer demand. However, the impact of faster delivery on how consumers place orders (their order frequency and basket sizes) and the subsequent environmental implications are not known. To investigate these questions, we leverage a quasi-experiment involving the opening of a new local warehouse by Alibaba Group, which led to a half-day improvement in the delivery speed for local orders. Through a difference-in-differences analysis, we find that the delivery speed improvement not only increased consumers' monthly purchasing amount by 6.70%, but also increased monthly order frequency by a higher percentage (i.e., 7.74%) and reduced the average order basket size by 0.79%. These results collectively suggest that with faster delivery, consumers purchase more on the platform but do so in more frequent and smaller orders, which implies more packaging and transportation costs for each unit of product sold. Based on these results, we conduct a detailed calibration using both public and company-specific data to estimate the increase in the platform's carbon emissions due to faster delivery. We also explore and identify two mechanisms contributing to the phenomenon: order-splitting and category expansion. We combine these insights with heterogeneous treatment effect analysis to derive managerial implications for the e-commerce platform. In particular, we find that for a platform that implements a threshold shipping policy, raising the free shipping threshold may be more effective than raising the shipping fee to reduce the environmental and operational costs associated with faster delivery.

Summit - 441

Retail Platforms and Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Yiwei Wang, Zhejiang University, Haining, N/A

1 - Modeling the Influence of Unpaid Effort in Delivery Agents' Choices in Last-Mile Platforms

Lina Wang, The Pennsylvania State University, State College, PA, United States, Stanley Lim, Elliot Rabinovich

We examine decision-making dynamics in the choices that delivery agents make among jobs available in last-mile platforms. Jobs at these platforms comprise the delivery of multiple orders along routes and their compensation typically accounts for the number of deliveries and the length of the routes involved in making these deliveries (from the first to the last delivery). Rarely, however, do jobs compensate agents for the distance they must travel to make the first delivery in the routes. This distance (typically referred to as stem distance, deadhead, or empty miles) often constitutes a significant portion of the effort agents put in to complete these jobs. We seek to determine how this unpaid effort influences job selection by agents relative to other job attributes. We obtained job selection data from a last-mile delivery platform and, based on this data, used a structural framework to estimate a dynamic choice model that accounts for the effects of stem distances and other job attributes on agents' job selection decisions. This model also considers the uncertainty agents face regarding the availability and quality of future jobs by accounting for the option value of waiting as well as dynamic selections among agents. We find that an increase in stem distances markedly reduces the likelihood of job selection, overshadowing job attributes such as payout amounts and delivery lead times. Additionally we find that the information available at the platform allowing agents to calculate stem distances induces greater selectivity among agents in favor of better paid jobs.

2 - Generative AI in Action: Field Experimental Evidence on Worker Performance in E-Commerce Customer Service Operations

Lauren Lu, Dartmouth College, Hanover, NH, United States, Xiao Ni, Yiwei Wang, Tianjun Feng

We investigate how generative AI tools affect worker performance. In collaboration with an e-commerce platform, we analyze a large-scale field experiment to uncover the impact of generative AI on worker productivity and service quality in an online retail after-sales service setting. Helping after-sales service agents in interacting with customers, the adoption of the generative AI tool reduces the average problem identification time and increases the average problem resolution rate. Meanwhile, we find that the tool improves service quality as reflected in increased customer ratings and satisfaction rates.

3 - Operations Strategies of Retail Platforms: Competing Through Logistics Service

Yao Li, Kellogg, Northwestern University, Chicago, IL, United States, Lauren Lu, Jan A. Van Mieghem

We study the operations strategies of retail platforms that provide logistics service to sellers. We develop a stylized game-theoretic model where two competing retail platforms provide both the marketplace and logistics services to a single seller. The platforms first decide their commission rates and logistics service fees, and the seller decides whether to sell on the platforms. As expected, we find that in equilibrium, the commission rates decrease as the competition between the platforms intensifies. Furthermore, there exists a strategic substitution between commission rates and logistics fees.

4 - The Value of Curated Boxes: Evidence from an Online Omnichannel Fashion Retailer

Yiwei Wang, Zhejiang University, Haining, China, People's Republic of

Curated boxes offer customers a carefully chosen assortment of products, allowing them to purchase desired items and return the rest. While this channel strategy enhances customer shopping experience, its impact on retailer profitability remains largely unexplored. Employing field experiment data from an online omnichannel fashion retailer, we examine the effects of introducing and terminating a monthly curated box program on customer behaviors in an online sales channel and a subscription rental channel. We observe that curated boxes boost omnichannel total sales due to (1) direct purchases from curated boxes, and (2) demand spillovers to the online sales and subscription rental channels. During the treatment period (i.e., after introducing the curated-box program), demand spillovers to the online sales channel are less than to the subscription rental channel. During the posttreatment period (i.e., after terminating the curated-box program), demand spillovers amplify in the online sales channel but decline in the subscription rental channel.

Organ Transplantation 1

Invited Session

MSOM: Healthcare

Chair: Diwakar Gupta, University of Texas, Austin, TX, United States

1 - Is the Targeted Placement of Deceased-Donor Kidneys Beneficial?

Paola Martin, Indiana University, Bloomington, IN, United States, Jingyao Huang, Diwakar Gupta

In the US, Organ Procurement Organizations (OPOs) are responsible for procuring deceased-donor organs, whereas Transplant Programs (TxPs) decide which organs to utilize for which candidates. OPOs typically make simultaneous offers for several candidates listed at a program in the strict priority sequence determined by national allocation rules. Higher-ranked candidates have the right of first refusal over lower-ranked candidates. TxPs are expected to make utilization decisions based on the merits of performing a transplant for each candidate independently of other candidates. We present evidence that this is not true in a significant number of cases. In fact, TxPs choose specific lower-ranked candidates for a subset of kidneys while skipping several higher-ranked candidates. The objective of this talk is to estimate the prevalence of such targeted placements (TPs) and quantify their impact on recipients and skipped candidates. We find that TPs have disparate impact on waitlisted candidates -- shortening the time on dialysis for TP recipients but lengthening it for skipped candidates. However, they have no significant effect on the 1-year post-transplant patient and graft survival among either group of candidates. Thus, the net benefit of TPs depends on the relative weights one would place on their positive and negative impacts.

2 - Interpretable Score Models for Predicting Discard Risk of Deceased Donor Kidneys

Osman Ozaltin, North Carolina State University, Raleigh, NC, United States, Ruoting Li, Sait Tunc, Matthew Ellis

Despite their growing shortage, more than 20% of the donated kidneys are discarded, a substantial proportion of which is due to organ quality and matching this quality to a recipient's needs. Therefore, mechanisms to expeditiously match available organs at higher risk for discard with patients that may benefit from these organs are critical. This study aims to predict the discard risk of deceased donor kidneys using interpretable models. We propose risk scores models using two approaches. First, we develop a discard risk score without using KDRI. In the second approach, we extend KDRI to estimate discard risk. We present a computational evaluation of prediction performance and drive key insights into factors affecting discard risk.

3 - The Impact of Competitive Entry in An Organ Transplant Market

Guihua Wang, The University of Texas at Dallas, Richardson, TX, United States, Jiayi Liu, Jun Li, Wallace Hopp

Using patient-level data from all centers for organ transplant in US, we provide empirical evidence that new entrants affect incumbents' risk-taking behaviors. We then develop an econometric model to analyze the impact of competitive entry on patients' waiting time and survival.

1 - Double Distributionally Robust Bid Shading for First Price Auctions

Yanlin Qu, Stanford University, Stanford, CA, United States, Ravi Kant, Yan Chen, Brendan Kitts, San Gultekin, Aaron Flores, Jose Blanchet

Bid shading has become a standard practice in the digital advertising industry, in which most auctions for advertising (ad) opportunities are of first price type. Given an ad opportunity, performing bid shading requires estimating not only the value of the opportunity but also the distribution of the highest bid from competitors (i.e. the competitive landscape). Since these two estimates tend to be very noisy in practice, first-price auction participants need a bid shading policy that is robust against relatively significant estimation errors. In this work, we provide a max-min formulation in which we maximize the surplus against an adversary that chooses a distribution both for the value and the competitive landscape each from a Kullback-Leibler-based ambiguity set. As we demonstrate, the two ambiguity sets are essential to adjust the shape of the bid-shading policy in a principled way to effectively cope with uncertainty. Our distributionally robust bid shading policy remains efficient to compute and systematically outperforms its non-robust counterpart on real datasets provided by Yahoo DSP.

2 - Dynamic Pricing and Bidding for Display Advertising Campaigns

Sami Najafi Asadolahi, Santa Clara University, Santa Clara, CA, United States, Naren Agrawal, Stephen Smith

Display advertising’s growth has transformed business engagement with target audiences. Despite its benefits, managing campaigns is challenging due to uncertainties in arrival rates, user visits, and real-time auction outcomes. We aim to devise an optimization method for agencies to profitably price and bid for campaigns while maintaining clients’ expectations. We formulate real-time bidding strategies for impressions or specific actions performed by viewers (e.g., clicks) and pricing strategies for new campaigns, through a Markov decision process to maximize profits. Through analysis, we offer valuable insights, demonstrating the efficacy of strategies based on campaign arrival intensity. We identify an optimal approach to allocating viewers to different campaign types based on their bids for viewers. Conceptually, this approach visualizes an internal market operated by the ad agency, where the various campaign types compete for viewers. To facilitate the implementation of our methodology, we also develop heuristic solution methods that can be scaled to accommodate the large numbers of viewer impressions or actions often requested in practice. We quantify the operational benefits resulting from combining campaigns that target similar viewer types, or merging similar ad agencies. This leads to higher profits for the ad agency, lower optimal prices, and reduced delays in delivering promised impressions or actions to campaigns. We present a practical, easily implementable heuristic that efficiently consolidates requested viewer impressions or actions into larger blocks, significantly reducing computation time while maintaining minimal impact on expected profit.

3 - Optimal Provision of Data via Collaborative Learning Platforms Under Competition

Mingxi Zhu, Georgia Institute of Technology, Atlanta, GA, United States

This study explores the merchants optimal provision of data samples via a collaborative learning platform, realizing the future potential competitive dynamics after data sharing. With the increasing recognition of data as a strategic asset, firms are confronted with the decision of whether to share their data with competitors, thereby potentially compromising their competitive advantage, or withhold it to maintain exclusivity at the expense of potential collaborative benefits. This work provides a novel framework to first explore the firms optimal decision on data sharing without platform intervention. Then, it studies how platform mechanism design on data sharing would induce a Pareto improvement among firms. The results presented in this paper shed lights in how to balance between the advantages of cooperative data sharing and the risks associated with divulging additional information to competitors, and provides insights for firms seeking to optimize their data sharing decisions in competitive markets.

Retail Analytics: Space and Assortment Planning

Invited Session

MSOM: Service Operations

Chair: Tulay Flamand, University of Colorado Denver, Denver, CO, United States

1 - Store-Wide Shelf Space Allocation under Health Safety Considerations

Tulay Flamand, University of Colorado Denver, Denver, CO, United States, Ahmed Ghoniem, Bacel Maddah

Given the increased public health concerns stemming from events like the COVID-19 pandemic, managing the health safety of public spaces such as grocery stores has become crucial. This study addresses a store-wide shelf-space allocation problem in grocery stores with a focus on health safety. We propose a mixed-integer nonlinear programming model that strategically allocates grouped product categories to shelves. This allocation guides in-store traffic and minimizes peak traffic density across all shelves, thereby reducing customer interaction and enhancing safety. We present our preliminary results to demonstrate the efficacy of our model.

2 - Pricing And Convenience Considerations In Omnichannel Assortment Planning

Joshua Gladstone, University of Massachusetts Amherst, Amherst, MA, United States

We address the problem of assortment planning and pricing optimization for omnichannel grocery retailers. In the proposed mixed-integer nonlinear program, the decision-maker jointly optimizes channel assortments and prices, endogenously driven by consumer price and convenience preferences, while accounting for limited brick-and-mortar shelf space and economies of scale incentives for the retailer. Linearizing our model enables computational analysis and provides managerial insights for simultaneously optimizing online and in-store product lines.

3 - Bi-objective Optimization for Store-Wide Shelf Space Allocation

Bacel Maddah, American University of Beirut, Beirut, Lebanon

We develop a framework for optimizing shelf-space allocation in grocery stores that balances impulse buying with shopping convenience. Our model, a bi-objective nonlinear integer program, is applied to a large supermarket in France. We propose a linearization scheme, and obtain the efficient frontier of Pareto-optimal solutions. Results show potential for significantly boosting impulse revenue while reducing customer inconvenience.

4 - Inventory control with FIFO and LIFO picking behavior

Anna-Lena Sachs, Lancaster University, Lancaster, United Kingdom, Thomas Vogt, Ulrich Thonemann, Ben Lowery

Customer picking behaviour plays an important role in retail inventory management. Standard inventory models usually distinguish between picking the newest items, i.e. Last-in-first-out (LIFO), or the oldest items first, i.e., First-in-first-out (FIFO). We analyze how LIFO and FIFO picking behaviour affects inventory management in retailing, and whether monetary and non-monetary incentives can change customer picking behaviour to increase sales of earlier expiring items and reduce food waste in retailing.

5 - Who gets the product? Channel Assortment and Inventory Allocation Strategy Design for an Omnichannel Retailer

Jia Guo, California State University-East Bay, Dublin, CA, United States, Iman Dayarian, Burcu Keskin

We explore the channel assortment and inventory allocation decisions for a dual-channel retailer that operates both physical and online stores. The retailer primarily fulfills online orders through distribution center deliveries and employs omnichannel strategies like Ship-from-Store and Buy-Online-Pickup-in-Store, leveraging in-store inventory to fulfill online orders. Despite competitive pressure to expand fulfillment channels, operational challenges increase fulfillment costs and decision complexity. Customers with different preferences on fulfillment channels are modeled through customer types. Each customer type corresponds to a specific preference order among fulfillment channels, with customers purchasing from their highest-ranked available channel. The retailer's challenge involves solving a channel assortment problem and determining which channels to offer customers. Simultaneously, inventory allocation decisions entail choosing a subset of the channel assortment for every sequentially arrived customer during the selling season to maximize expected profit. Our analysis reveals that adding fulfillment channels through omnichannel strategies can reduce profits due to customers' stockout substitution behavior, highlighting the role of demand information and dynamic rationing in mitigating these effects and maximizing the benefits of implementing omnichannel strategies. Dynamic rationing allows retailers to adjust their decisions in response to real-time sales data, providing flexibility and adaptability. Our findings suggest that a dynamic rationing policy, developed with limited demand information, may outperform a static allocation policy based on precise demand information in specific scenarios.

Supply Chain Finance and Fintech

Invited Session

MSOM: Supply Chain

Chair: WENTING LI, Arizona State University, Tempe, AZ, 85044-1746, United States

Co-Chair: Rafael Escamilla, Arizona State University, Tempe, AZ, United States

Co-Chair: Rafael Escamilla

1 - Text Beyond Text: How Short Videos' Sentiment Impact Stock Market

Yifan Ren, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Qiyu Dai

With the growing availability of financial news on short video platforms, the sentiment in the videos is affecting investors' attitudes towards the performance of firms. Such an impact can be reflected in the return of stocks. In this paper, we aim to examine the impact of short videos' sentiment on the future return of stocks for a rich set of companies. We extract the texts in all videos posted by some official financial news accounts. Based on the tag of videos, we match each video to firms it discusses. Then, each videos' anticipation towards the future trend of stocks as either "Long" or "Short" based on their textual information using with the help of large language models. A comparison of the stock return between the two groups reveals that companies that are categorized as "Long" have slightly higher future returns, highlighting the importance of short video financial news on the stock market. Our study provides managerial implications for both stock investors and listed companies.

2 - Supply Chain Finance and Payment Practices: a Dyadic Perspective

Yiyi Fan, Lancaster University, Lancaster, United Kingdom, Fang Li, Mark Stevenson, Shantanu Banerjee

This research examines the effect of supply chain finance (SCF) on payment practices from a dyadic, buyer-supplier perspective. We exploit current UK policy, which mandates that larger businesses must disclose their payment practices, including whether they make SCF available to their suppliers, to obtain a buyer-supplier matched sample. We examine whether using SCF offered by disclosing buyer firms affects their payment practices, including late payments to suppliers. We find that SCF is positively associated with the average payment time of buyers and with a lower proportion of free-of-charge fast payments, suggesting SCF is a trade-off decision for suppliers between speed of payment receipt and cost. Moreover, firms offering SCF have a higher proportion of late payments, i.e. invoices that are not paid within the agreed payment period, and are more likely to negotiate a longer contractual payment period with their suppliers. We also find that using SCF is negatively associated with suppliers' receivable days, suggesting suppliers could indeed obtain faster payments through SCF but must bear the cost. Collectively, our results suggest that SCF initiated by large buyer firms may speed up payment receipt for suppliers in general, but the problem of late payments becomes worse for suppliers unless they pay a premium to receive what they are owed. The findings challenge the prevailing assumption that SCF is beneficial and point to the potential risk of creating more adversarial buyer-supplier relationships.

3 - Supply-Chain Finance: An Empirical Evaluation of Supplier Outcomes

Yingjie Qi, Copenhagen Business School, Copenhagen, Denmark, Niklas Amberg, Tor Jacobson

Buyers and suppliers have diverging interests about trade-credit maturities: buyers desire long payment periods as a source of cheap funding, while suppliers prefer swift payments to avoid locking up scarce liquidity in idle assets. A fast-growing financial product innovation---supply-chain finance (SCF)---offers to resolve these diverging interests, but its net effect on suppliers is a priori unclear. We study the effects of SCF programs on suppliers using unique invoice-level data from a large Swedish bank. We find that SCF programs relax suppliers' liquidity constraints and thereby enable them to grow their sales, employment, and investments.

Advances in Operations Management

Invited Session

MSOM:Technology, Innovation, and Entrepreneurship

Chair: Eryn Juan He, University of Utah, Salt Lake City, UT, United States

1 - FinTech Lending, Open Banking, and Consumer Manipulation

Yangguang Wang, Syracuse University, Syracuse, NY, United States, Zhengping Wu, Fasheng Xu

Ensuring equality of opportunity is pivotal for personal development. Nevertheless, roughly 3 billion disadvantaged individuals worldwide are hindered from realizing their full potential due to inadequate access to financial services. Over the last decade, fintech companies have been at the forefront of addressing this issue by leveraging alternative data for credit scoring. Despite notable progress, challenges persist, particularly regarding the manipulation of alternative data by individuals. Against this backdrop, Open Banking is emerging on a global scale, with the goal of enabling the free sharing of banking data and thus promoting financial inclusion. To examine the effects of Open Banking on fintech companies' services for disadvantaged populations, we introduce a game-theoretical model wherein individuals strategically decide whether to manipulate their alternative data to secure a loan from fintech lenders. Although Open Banking enables fintechs to access individuals' additional data source – banking data, we raise a main concern. Making such banking data available to fintech lenders may alter consumers' manipulative behavior in a way that dilutes the information contained in the original alternative data source, thereby making the fintech less efficient at evaluating individuals' default risks. The information asymmetry between these two parties may become more severe, leading to a more conservative lending practice of the fintech lenders, and ultimately weakening financial inclusion.

2 - A Framework for New Venture Creation

Zhengli Wang, The University of Hong Kong, Hong Kong, Hong Kong, Stefanos Zenios

We model the creation of a new venture with a diffusion control framework. The state of the venture is captured by a diffusion process. The entrepreneur chooses between two controls that determine the drift and the variance of the process. Depending on whether the process reaches the upper or the lower boundary, the venture succeeds or fails. The entrepreneur wishes to maximizes the expected total payoff. We derive the optimal policy and show that the gap between using the optimal policy and using the best single control is small.

3 - Optimal Contract Design under Multiple Moral Hazard - Ex Ante, Ex Post Cash Diversion, and Price Deviation

Ruiting Zuo, Financial Technology Thrust, The Hong Kong University of Science and Technology (Guangzhou), Guangzhou, China, People's Republic of, Mingliu Chen, Feng Tian

We consider a decentralized newsvendor production problem subject to agency issues. A principal funds and contracts with an agent for production planning. However, the agent is subject to moral hazard, such as cash diversion during different stages of a production process, which is unobservable to the firm. We derive the principal's optimal contract and corresponding operational decisions under ex ante and ex post cash diversion scenarios, which happen before and after demand is realized, respectively. When only subjected to ex ante diversion, the optimal contract is a debt contract, which leads to underproduction and a higher price than that under first-best centralized production. When subjected to both ex ante and ex post diversion, the debt contract is no longer optimal. Instead, we present a modified debt repayment that resembles both debt and revenue-sharing contracts, which is optimal. Furthermore, we find that the optimal capacity and price depend on the level of ex post diversion efficiency with respect to which the optimal price is nonmonotonic. Finally, we consider a scenario where the actual sales price is also unobservable and find that the principal can still use a contract similar to debt to deter ex ante diversion and price deviation in most regimes. However, this contract must have an additional clause penalizing excessive revenue. All optimal contracts in this paper have simple forms and are easy to implement. We highlight the optimal operational decisions, such as the optimal capacity and price, accompanied by the financial decisions.

4 - Ethics and Platform Responsibility

Nabita Penmetsa, University of Utah, Salt Lake City, UT, United States, Manu Goyal, Krishnan Anand

Should platforms voluntarily assume responsibility for losses incurred by consumers in the absence of legal mandates?. To answer this question, we develop a finite-horizon model of a platform market with the platform, agents, and consumers. The platform is either ethical or unconstrained and is called into action whenever a consumer incurs a loss. The agents are short-run and control both the choice of effort and prices. Consumers are strategic and play a critical role in revealing the platform type by posting reviews. We show that an ethical platform, one that assumes responsibility voluntarily by compensating the consumer for losses, outperforms a platform unconstrained by such ethics. Moreover, the mere possibility of ethical platforms in the population can increase effort and prices over time.

We show that without reviews, even an ethical platform cannot induce agents to exert effort, and prices remain forever low. However, when consumers post reviews with some probability, however small, even an unconstrained platform can induce agents to exert effort and cause prices to increase over the horizon. When number of periods is large, it is indeed optimal for the unconstrained platform to assume responsibility and protect consumers from losses.

5 - Dissecting the Learning Curve for Supply Chain Efficiency and Stability: An Empirical Analysis

Mengfei Li, Fudan University, Shanghai, China, People's Republic of, Yue Cheng, Liu Ming, Xiaole Wu, Wenchang Zhang

Our study explores learning effects in the supply chain and production processes of small/median sized manufacturing firms(SMEs) on both efficiency and stability. We focus on the enhancement of four key supply chain stages - upstream supply chain, scheduling, production, and downstream supply chain - through learning, and the impact of learning materials(historical orders) factors and spillover effect on learning effectiveness. The research is grounded in a rich dataset from dozens of SMEs manufacturing firms, allowing for precise tracking of each production process's timeline and various pieces of information.We employ a range of empirical strategies to analyze how production efficiency and stability evolve as firms' experience accrues. We further reveal underlying mechanisms by examining the learning effects of orders' batch sizes and urgency, as well as potential heterogeneous spillovers among different product lines. These insights offer practical recommendations for managerial optimization, leading to improved organizational effectiveness, and underscore the vital role of continuous learning in enhancing manufacturing efficiency and stability, a critical determinant of the competitiveness of order-responsive enterprises.

1 - Labor Implications of the Energy Transition: Assessing Transforming and Emerging Industries

Jillian Miles, Carnegie Mellon Unviersity, Pittsburgh, PA, United States

Amid global efforts to mitigate climate change, large industries are facing increasing pressure to decarbonize, particularly in heavy manufacturing sectors such as iron and steelmaking, while emerging 'green' industries, like battery manufacturing for electric vehicles, are working towards greater prominence. However, these technological shifts, driven by the broader energy transition, could profoundly affect local labor markets. This analysis presents two case studies that integrate industry and jobs data with occupational characteristics to evaluate how technological advancements or growth may impact local labor dynamics. The first case examines the iron and steelmaking industry, focusing on the shift from high-emitting blast furnace "integrated" production to low-emitting electric arc furnace (EAF) processes. Our findings indicate that while traditional iron and steel workers possess the necessary skills for EAF production, less than half of the original workforce is required to sustain the new operations, putting a significant number of production workers at risk of unemployment. The second case study explores the labor readiness of various U.S. locales considering incentivizing battery manufacturing, by measuring the possible shock adding a small or large battery gigafactory would have on a given area. Preliminary results show varied readiness for both sizes of factories and explores overlaps with disadvantaged communities and energy communities. Both studies provide critical insights for policymakers, highlighting the potential need for skills training and wage insurance, and underscore the importance of centering community needs in the analysis.

2 - Learning by Doing Different Gigs: Uncovering Latent Skill Development on Online Labor Platform

Guanting Wu, Carnegie Mellon University, Pittsburgh, PA, United States, Peter Zhang, Hai Wang

Problem definition: Online labor markets (OLMs) are experiencing rapid growth, in which online labor platforms help clients and workers find each other based on relevant skills necessary to complete projects. Their online interactions reveal the learning trajectories of individual workers by doing different gigs. In this paper, we uncover how workers develop skills and how their diverse skills interdepend on online labor platforms. Methodology: We propose a partially observable Markov process (POMP) framework and instantiate it to a parameterized multivariate linear-Gaussian model. We also identify a sampling selection bias in discrete-time data, which motivates model design. Due to the intrinsic data sparsity, we estimate the parameters of the multivariate model using a two-stage solution approach. Results: Using a proprietary and large-scale dataset containing millions of transactions over a 12-month period from a leading online labor platform, we apply our method to gain insights into the skill development of workers and the interdependence of diverse skills. First, workers develop their skills through the completion of increasingly complex projects. Second, we observe a significant interdependence between project and skill categories. Third, project complexity negatively affects service quality. Managerial implications: Based on our findings, we propose that online labor platforms could design growth-aware recommendation systems and broaden the criteria for worker recommendations considering their diverse skills. In addition, platforms could encourage clients to decompose projects into several sub-projects to reduce project complexity.

3 - Robust contract design and linear contract optimality framework

Michelle Wang, Carnegie Mellon University, Pittsburgh, PA, United States, Peter Zhang

tbd

4 - Analyzing the Gig Economy via Agent-Based Modeling with a Focus on Gig Workers Challenges

Tara Eslaminokandeh, Northeastern University, Boston, MA, United States, Kunind Sharma, Ozlem Ergun, Michael Kane

With the expansion of the gig economy and the use of digital platforms in recent years, sectors such as transportation and accommodation are highly impacted. Although this growth offers numerous advantages, it also presents considerable drawbacks that must be addressed and resolved. Most studies in this area tend to focus on the perspectives of platforms and customers, often overlooking the interests and challenges faced by workers, such as information asymmetry, which negatively impacts gig workers and complicates their decision-making processes.

In this study, we analyze the gig economy by focusing on addressing the critical challenges and concerns from the perspectives of gig workers. Specifically, we employ an agent-based modeling (ABM) method to simulate the behaviors and interactions of stakeholders in the gig economy—workers, customers, and platforms—to study the impact of these interactions on both the system and the individuals involved. Our methodology comprises three phases: collecting data through surveys and interviews, developing an ABM simulation model based on this data, and designing and conducting experiments to analyze various scenarios within the gig market. We particularly examine worker responses to different policies and systemic changes. This approach contributes to a comprehensive understanding of the gig economy, emphasizing the importance of addressing worker concerns and developing equitable policies to support a more sustainable gig economy.

Our findings aim to inform policymakers and platform designers about the effects of their decisions on all stakeholders, helping them to ensure that the gig economy benefits workers, customers, platform companies, and society simultaneously.

Equity in Health Decision-Making: Navigating the Future Together

Invited Session

Health Applications Society

Chair: Gian-Gabriel Garcia, Georgia Institute of Technology, Atlanta, GA, United States

Co-Chair: Amaya McNealey, Georgia Institutue of Technology, Atlanta, GA, 30318, United States

1 - Race-Neutral Calculator Still Disadvantages Black Patients

Amaya McNealey, Georgia Institute of Technology, Madison, AL, United States

There has been a longstanding concern in healthcare about the appropriateness of using race and ethnicity in predictive algorithms to facilitate prognosis, diagnosis, and treatment. Specifically, the VBAC calculator is a clinical decision support tool to identify if patients who have previously experienced a low-transverse cesarean delivery are eligible to be recommended a trial of labor after cesarean (TOLAC) or if they are recommended a repeat cesarean delivery. The original VBAC calculator created in 2001, “VBAC 1.0”, faced criticism after explicitly using race/ethnicity as a variable within the model. To replace VBAC 1.0, “VBAC 2.0” was created in 2021, removing the use of race/ethnicity and adding an indication of treated chronic hypertension. However, while the statistical performance of VBAC 2.0 was similar to VBAC 1.0, it is not explicit to what extent VBAC 2.0 shifts risk scores for racial groups and subsequently how these updated predictions affect the likelihood of recommending a TOLAC. To compare the effects of both calculators, we conducted a secondary analysis of pregnant patients who had a prior low transverse delivery at Grady Memorial Hospital in Atlanta, GA. Our results show that 34.0% of Non-Hispanic Black patients would have been recommended a cesarean delivery due to the VBAC-1.0 compared to 60.7% under VBAC-2.0 (Likelihood ratio (LR): 1.78; 95% CI: 1.52-2.10). For non-Hispanic Black patients, the increased likelihood of a cesarean recommendation remained regardless of their respective hypertension status, indicating that additional research in machine learning fairness is crucial to ensure equitable shared decision-making and downstream effects.

2 - Fairness-Promoting Stochastic Facility Location

Karmel Shehadeh, Lehigh University, Bethlehem, PA, United States

Uneven distributions of healthcare facilities across different regions lead to disparities in accessibility and transportation distance to health services. To mitigate such disparities, we propose fairness-promoting stochastic optimization methodologies for the stochastic fixed-charge facility location problem. Our results show, for the first time, how different methods of modeling fairness under uncertainty can result in different location decisions with varying impacts on fairness. In addition, they underscore the potential of the proposed approaches to enhance fairness in facility location.

3 - The Utility and Fairness of The Inclusion of Race in Cardiovascular Risk Prediction Algorithms

Noah Hammarlund, University of Florida, Gainesville, FL, United States

Cardiovascular disease (CVD) remains a leading cause of mortality worldwide, with risk prediction algorithms playing a pivotal role in risk assessment and intervention by matching prevention efforts to individual needs. Recent debates have surfaced regarding the exclusion of race as a variable in these CVD prediction algorithms due to concerns about perpetuating biological racism in clinical practice. Concurrently, there is growing interest in integrating social determinants of health (SDoH) into prediction models in place of race. However, the impact of excluding race on the utility and fairness of CVD prediction models remains uncertain, prompting the need for a critical reevaluation. This study investigates utility and fairness considerations surrounding the exclusion of race and the potential integration of SDoH in cardiovascular risk prediction models.

Using the CARDIA (Coronary Artery Risk Development in Young Adults) dataset, this study compares the predictive efficacy of CVD risk prediction algorithms with and without race as a predictor. The study also explores the ethical and fairness implications of SDoH-informed algorithms by comparing models with SDoH predictors to traditional models with race. Given recent concerns about the fairness of race-based risk assessments, the research seeks to determine whether the replacement of race with SDoH predictors may alleviate or exacerbate existing health disparities.

Through a comprehensive analysis, this study aims to inform evidence-based decision-making in cardiovascular medicine. By leveraging insights from the CARDIA dataset, it strives to develop ethically sound recommendations for risk prediction models that balance accuracy and equity, ultimately improving health outcomes for diverse populations.

4 - Personalized Visit Planning for Patients with Chronic Disease

Katherine Adams, University of Wisconsin-Madison, Madison, WI, United States, Justin Boutilier, Sarang Deo, Yonatan Mintz

Approximately 240 million people are living with undiagnosed diabetes globally. Among these, almost 90% reside in low- and middle-income countries (LMICs), leading to a large proportion of people with unmanaged blood glucose levels. Effective interventions require the joint planning of screening and management visits. Community Health Worker (CHW) programs provide an affordable and culturally tailored solution for early detection and management of diabetes whilst expanding health system capacity. We propose an optimization framework to personalize CHW visits, tradeoff screening and managing patients, and maximize glycemic control. By modeling patient motivational states, we also anticipate and prevent drop out decisions for enrolled patients. We present structural and computational results using real data from India.

5 - Addressing Subgroup-Specific Bias Using Multi-Level Approaches and Causal Inference

Vishwali Mhasawade, New York University, New York, NY, United States

While a patient visits the hospital for treatment, factors outside the hospital, such as where the individual resides and what educational and vocational opportunities are present, play a vital role in the patient's health trajectory. On the contrary, most advances in machine learning in healthcare are mainly restricted to data within hospitals and clinics. Moreover, data is limited chiefly to observed factors assumed to be proxies for the quantities of interest. While health equity, defined as minimizing avoidable disparities in health and its determinants between groups of people with different social privileges in terms of power, wealth, and prestige, is the primary principle underlying public health research, this has been largely ignored by the current machine learning systems. Inequality at the social level is harmful to the population as a whole. Thus, focusing on the factors related to health outside the hospital is imperative to address specific challenges for high-risk individuals and determine what policies will benefit the community as a whole. In this talk, I will first demonstrate the challenges of mitigating health disparities resulting from the different representations of demographic groups based on attributes like gender and self-reported race. Next, I will present a causal remedial approach to health inequity using algorithmic fairness that reduces health disparities. Ultimately, I will discuss how the appropriate choice of labels used for training machine learning algorithms can impact fairness considerations.

Summit - Terrace Suite 2

OR Applications for Medical Decision-making

Invited Session

Health Applications Society

Chair: Daniel Otero-Leon, Harvard Medical School / University of Virginia, Boston, MA, United States

1 - Evaluating Disparities in Colorectal Cancer (Crc)

Bryan Ortiz Torres, University of Wisconsin Madison, Madison, WI, United States, Gabriel Zayas-Caban

Health disparities in colorectal cancer (CRC) patients have been widely documented. While CRC incidence rates have decreased during the past decades, differences between non-Hispanic black and non-Hispanic white individuals still exists. Here, we present our work on analyzing disparities for CRC patients using survival analysis and data from the Southern Community Cohort Study (SCCS).

2 - Clustered Multi-Task Learning for Prediction of Adverse Pregnancy Outcomes

Sun Ju Lee, Georgia Institute of Technology, Atlanta, GA, United States, Gian Garcia, Kaitlyn Stanhope, Marissa Platner, Sheree Boulet

In clinical prediction models, combining individual indicators into a composite outcome can help overcome issues associated with single outcomes such as low predictability and low prevalence. However, this may obscure relationships between predictors and single outcomes, and may limit the clinical utility of the prediction model as diagnoses may have different etiologies addressed by different interventions. We aim to resolve this trade-off by developing an optimization framework to simultaneously cluster related outcomes and learn model parameters for each cluster. We apply our formulation to indicators comprising maternal and neonatal morbidity and demonstrate that our approach can aid interpretability by finding underlying groups of related tasks and deriving an interpretable set of predictors.

3 - Analyzing the Dynamics of Overdose Death Spikes by Substance Across Massachusetts Counties

Daniel Otero Leon, Harvard Medical School, Boston, MA, United States, Mohammad Jalali, Huiru Dong, Hannah Lee

Overdose death data trend analysis often consists of yearly aggregate trends or rates, which may mask short-term fluctuations. Emergency responders often report that periods of calm are followed by a sudden rise, or spikes, in overdoses, which suggests that the risk of death can change substantially in a short period. Multiple substances are involved in overdose death, and it will be crucial to know if certain substances increase the likelihood of a spike. This study aimed to analyze at a county level in Massachusetts which substances are involved more during spike days. We count with overdose fatalities from the Massachusetts Registry of Vital Records and Statistics from 2017 to 2022. We employed a peak detection algorithm based on z-scores that identifies deviations from the established patterns within a dataset. We then applied t-tests in select counties to compare substance prevalence between spike and non-spike days.

Amazon Warehouse Resource Optimization

Invited Session

The Practice Section of INFORMS

Chair: Xinyu Fei, Amazon.com, Bellevue, WA, 98004, United States

1 - Labor Staffing in Amazon Sortable Fulfillment Centers

Yingqiu Zhang, Amazon, BELLEVUE, WA, United States

When customers place the order through Amazon.com, associates in Fulfillment Centers (FC) will prepare the package for shipments. There are hundreds of associates in an FC works in various processes to ensure the orders are delivered to customers' doorsteps on time. Amazon FCs are powered by technologies to effectively staff associates to processes by optimizing associate experience, reducing associate injuries, lowering cost, and maximizing the volume throughput. Picking is a critical department in ARS FCs that holds the inventory storage and allows associates to pick the right inventory items to fulfill shipments. Associates are staffed stationary at picking stations, pick required items from the inventory pods moved by robotic drives, and place picked items into totes that will be sent to downstream for further processing.Staffing problem is complex at Amazon. Due to FC's physical layout, different picking stations have different priority, and there are multiple different types of picking stations, which have their unique staffing rule. Moreover, Amazon values associates health and perform safety rotations to reduce injuries and Amazon also respects associates' accommodations for best associates' experience. In this presentation, we present an optimization model to effective staff associates in FC, and more specifically, in picking department. The problem is formulated as mixed-integer goal programming that respects business and associates' rules and optimizes picking floor performance in business priority. This model has been launched across Amazon FCs by April 2024 and improved picking floor throughput and associates experience.

2 - Real-TIME Staffing Plan Adjustment in Fulfillment Centers

Xinyu Fei, Amazon, Bellevue, WA, United States, Andrew Johnson

Amazon's fulfillment centers (FCs) play a crucial role in ensuring efficient and timely delivery of orders placed by customers. These state-of-the-art facilities employ hundreds of associates working across various processes to prepare packages for shipment. Effective staffing in these fulfillment centers directly impacts associates' working experience, operational costs, and delivery time. One of the most important systems in Amazon FCs is the multi-products packing system. Because workers have varying levels of efficiency and conditions in the system can change, adjusting worker staffing in real-time is highly required. We build a non-linear mixed-integer optimization model that considers the multi-products packing system status and business needs to optimize worker staffing. Furthermore, we've proposed a heuristic method to provide a real-time staffing solution to improve user acceptance in practice.

3 - Same Day Outbound Resource Planning

AARON HERMAN, Amazon, Seattle, WA, United States

A high quality and accurate resource plan is a crucial component for a successful shift in an Amazon Fulfillment Center (FC). Without a high quality plan, resources will not be properly utilized to process shipments in time for the customer in the most efficient manner. Without an accurate plan, other systems or warehouse operators themselves will not have the information they need to identify a capacity constraint and actions to correct for it. In this presentation we will go over the main ideas and challenges behind producing these plans for Amazon FCs.

4 - Outbound Flow Management Systems

Maximilian Zellner, Amazon, Santa Monica, CA, United States

Amazon.com continues to improve delivery speed and to reduce cost. One key initiative of Amazon Fulfillment Technology contributing to these goals is the improvement of flow between processes in the outbound area of fulfillment centers. In this area, picking and packing processes are separated by conveyance with uncertain cycle times, and the downstream processes constitute the system's bottlenecks. To achieve good flow and low costs, a control model should aim to achieve high utilization of the bottleneck resource while keeping WIP low to produce favorable cycle times. We propose a linear programming model that explicitly models flow between the picking and packing processes, and controls the amount of work at the bottleneck process by setting upstream pick throughputs.

5 - Modeling Flow in Fulfillment Centers

Andrew Johnson, Amazon, Bellevue, WA, United States, Maz Zellner

As Amazon continues to increase customer delivery speeds, modeling flow within the fulfillment center is critical. Amazon Fulfillment Technology is redesigning the flow management service to model explicitly buffer targets and cycle time within the fulfillment center. The flow management service models picking, the upstream process, that feeds multiple downstream packing processes. A critical input to the new service is the estimates for minimum, target, and maximum buffer sizes. The minimum buffers are calculated by estimating units per hour as a function of the buffer size. While a copula model is used to estimate the target buffer size. The maximum buffer sizes are calculated based on historical observed maximum buffer sizes.

Social Media Dynamics and Data Analysis

Contributed Session

Chair: Anna Gao, Philadelphia, PA, United States

1 - Dynamics of sentimental involvement on social media during crisis events: case studies in China

boyu zhu, Shanghai Maritime University, Shanghai, China, People's Republic of

This study explores the dynamic features of social media users' sentiment over popular issues in China. We selected eight popular incidents in China for case studies, and over 200,000 Sina Webos were analyzed. We found that there were three phases of the group sentiment. For each stage, official accounts and grassroots accounts are significantly different. Groups with highly polarized sentiments are detected, posing big challenges for crisis managers. Other managerial insights are discussed.

2 - Optimal News Search and Reporting

Weize Yin, University of Minnesota - Twin Cities, Minneapolis, MN, United States, Yi Zhu

One consumer's belief of an event may frequently fluctuate as she encounters different news reports during her news search on a news medium. In this paper, we investigate how a news medium strategically chooses its news reporting slant to maximize online consumer engagement and, consequently, digital advertising revenue. The consumer not only values more certain updated beliefs due to news search but also prefers news that aligns more with her inherent attitude. By establishing a micro foundation for the consumer's sequential news search, we model a Bayesian consumer's belief update based on Brownian motion. We explicitly characterize the expected duration of the consumer's news search, allowing us to examine the news medium's optimal slant. We find that a consumer stops her news search if her belief becomes sufficiently certain. A sufficiently strong attitude tends to prolong a consumer's news search time, even if the medium's slant opposes this attitude. Counterintuitively, we find that the news medium tends to be more slanted if the consumer values information learned from news search more. This is because the medium can utilize news slant to obfuscate the consumer's information learning, thereby retaining the consumer for a longer duration.

3 - Exploring the Dynamics of Hashtag Use and Comment Toxicity on Social Media

Anna Gao, University of Pennsylvania, Philadelphia, PA, United States

The advent of social media has revolutionized how information is disseminated and discussed globally. This project explores the role of informational cues, such as hashtags used by content creators, in fostering safe online communities, with a particular focus on comment toxicity in social media discussions. Using Twitter's API, we collected tweets and engagement metrics from a week-long sample, and used the Trump Trial as an initial case study. We aim to understand what drives toxic comments during ongoing, high-profile events. In particular, we apply zero-shot learning to classify tweets into categories of support, opposition, or neutrality towards Trump and discover that tweets opposing Trump receive higher engagement and more negative sentiment. Additionally, we assess hashtag relevancy using a pre-trained language model and find that higher relevancy scores correlate with increased tweet impressions, while greater variance in relevancy scores reduces engagement. Our preliminary analysis reveals key insights into hashtag relevancy and comment toxicity. There is a negative correlation between average relevancy and the proportion of toxic comments, indicating that the more relevant the hashtags are to the tweet's content, the smaller the proportion of toxic comments. The findings suggest that strategic use of relevant hashtags can mitigate toxic interactions, fostering healthier online discussion. By understanding and leveraging these dynamics, content creators can make smarter decisions to create a safer digital world.

4 - Tourism Forecasting with Multimodal Social Media Data: An Explainable Machine Learning Framework

Xin Li, University of Science and Technology Beijing, Beijing, China, People's Republic of, Xiangbin Yan

The rapid rise of social media platforms has provided a rich source of multimodal data, containing valuable insights that influence consumer decision-making. While existing research predominantly examines the impact of online reviews on tourism decisions, there is limited exploration into the joint analysis of text and image modalities, resulting in a lack of development of a comprehensive and interpretable analytical framework. This study proposes a novel explainable machine learning framework comprising aspect-based sentiment analysis for textual data, residual neural networks for image features, and long short-term memory models with attention mechanisms for accurate forecasting. Leveraging multimodal data from social media platforms including Ctrip, this research extracts diverse features from online reviews and images, examining how these features influence the forecasting of volumes at Jiuzhaigou tourist attraction. Findings reveal that the incorporation of textual and visual modalities enhances the accuracy of tourism demand forecasting, with varying degrees of improvement in forecasting efficacy attributable to different modalities of information. This research contributes to advancing the understanding of multimodal data analytics and underscores the importance of integrating text and image data for achieving smarter decisions in destination management.

Machine Learning in IS: Biases and Model Improvement

Invited Session

Information Systems

Chair: Wei (Weiguang) Wang, Johns Hopkins University, Rochester, NY, United States

1 - When Systemic Biases Taint Algorithms: A Path to More Equitable Access in Healthcare

Ozgur Aksoy, The University of Texas at Dallas, Richardson, TX, United States, Mehmet Ayvaci, Asunur Cezar, Srinivasan Raghunathan

While predictive algorithms hold promise for improving resource allocation decisions in socially critical contexts, they often exhibit "algorithmic bias," inadvertently favoring the socially advantaged. Current bias mitigation strategies typically focus solely on correcting predictions, neglecting downstream effects on subsequent decisions and the underlying societal disparities perpetuating this bias. We investigate the effects of algorithmic bias stemming from societal disparities within an integrated prediction-decision framework. Specifically, we assess how explicitly incorporating social factors into prediction-decision pairs influences outcomes, particularly for a healthcare payer's decision to allocate care management programs to beneficiaries at risk of high costs. We first theoretically model the payer's allocation decision and compare outcomes when adjusting predictions using social factors versus not. While adjustments can mitigate the negative impact of algorithmic bias during the prediction stage, reducing bias does not necessarily decrease disparities in decision outcomes, especially when variations in intervention effectiveness exist between advantaged and disadvantaged. Moreover, tight budget constraints on intervention can diminish the value of adjustments for outcome disparity reduction. Using Medicare insurance payments and CDC Social Vulnerability Index data, we develop a predictive algorithm, quantify algorithmic bias, and propose an adjustment method sensitive to societal disparities. Our results demonstrate this method enhances fairness (i.e., 27.03% increase in the number of disadvantaged beneficiaries among intervened) while simultaneously improving decision efficiency (i.e., replacing 8.20% of intervened beneficiaries with others having 18.65% higher future healthcare costs). Although we focus on health insurance, our approach could apply to other socially and economically significant contexts within and beyond healthcare.

2 - Enhancing Knowledge Retention in Knowledge Graph

Chaofan Zhai, University of Minnesota, Minneapolis, MN, United States, Yicheng Song, Ravi Bapna

Our research investigates a deep-learning framework to improve knowledge retention on online learning platforms. We address challenges in predicting knowledge retention, engagement, and optimizing long-term learning outcomes using a combination of knowledge graphs and transformer models. Our approach integrates static and dynamic knowledge graphs with embeddings derived from user interactions and predefined semantics. Additionally, we employ reinforcement learning to recommend learning paths that balance engagement and performance. Empirical results from MaiMemo.com, a major English learning platform in China, show our KG_Trans model achieves superior performance with an accuracy of 0.792 and an F1 score of 0.858. Future work will evaluate the performance of survival models and reinforcement learning in real-world settings. This research contributes to personalized and effective online learning, potentially applicable to various educational contexts.

3 - Key Verbatim Extraction from Clinical Notes: A Hierarchical Multimodal Cross-Attention Approach

Feiyu E, Robert H. Smith School of Business, University of Maryland, College Park, MD, United States, Hanwen Shi, Jin Zhang, Kunpeng Zhang

Clinical notes are pivotal for physicians to accurately assess patient conditions, particularly in oncology where records are extensive. Efficient information extraction from these notes is crucial for effective treatment. Quickly understanding clinical notes remains challenging due to their specialized content and extensive length. Current methods do not fully utilize relational information among sentences or across different notes, and the exploration of relationships among health-related entities is insufficient. We introduce a hierarchical multimodal cross-attention model that utilizes a cross-attention mechanism to integrate textual knowledge with patient network knowledge. It aims to synthesize information across various data levels, including word, sentence, note, and patient level, to efficiently highlight key sentences in clinical notes. Initial testing shows the model achieving a higher accuracy compared to baseline models, indicating effective learning but highlighting a need for better generalization. Enhancements will include integrating multimodal data, refining network knowledge, implementing regularization techniques, and optimizing learning parameters to improve model generalizability. This study offers a novel approach to clinical text analysis by combining multiple data levels and utilizing inter-patient relationships, potentially improving healthcare delivery and decision-making efficiency.

4 - The Risk of Inferring Data Insights from Post Hoc Explanations of Machine Learning Models

Ronilo Ragodos, University Of Iowa, Iowa City, IA, United States, Tong Wang, Jeffrey Hu, Lu Feng

The integration of machine learning (ML) methods in business research has seen a notable rise, prompted by the necessity to analyze complex datasets. While ML models are adept at making predictions, business researchers often seek an understanding of the underlying data. As post hoc explainers, such as SHAP and LIME, have emerged as popular tools to explain ML models, it has become increasingly common in business research for authors to use explainers to make inferences about their datasets rather than their models. This paper critically examines this trend. Specifically, we investigate whether post hoc explanations contain three types of information about the marginal effects of features in data that researchers seek, based on recent literature. We formalize the three types of information and refer to explanations that can capture them as data-aligned. We identify factors within the explanation pipeline that are associated with explanations that are not data-aligned. We find ideal conditions where LIME explanations are data-aligned, and we show theoretically that SHAP is inherently unsuited for recovering marginal effects. We also discuss the issue of explanation inconsistency, which is due to varying choices of models, explainers, and their configurations. Furthermore, we propose simple mitigation strategies for low data-alignment and inconsistency that we encourage researchers to use as a foundation for experimentation. We validate our mitigation strategies in an econometric context and demonstrate the resulting improvement in explanation quality. Despite these efforts, we nevertheless conclude that researchers should only use post hoc explainers to infer data insights with great caution.

Unlocking the Digital Discourse: From Data to Insights

Invited Session

Social Media Analytics

Chair: Priyanga Gunarathne, University of Pittsburgh, Pittsburgh, PA, United States

1 - Social Interaction Network Driving Purchase Behavior

Yoonjin Choi, Georgia Institute of Technology, Atlanta, GA, United States, Mingfeng Lin

E-commerce is increasingly social, with many different channels through which influencers and consumers may interact with each other, either before or after a purchase. Existing research, due to a lack of data or methodological constraints, often cannot fully account for the various ways through which online purchases take place. We investigate the extent to which purchases occur after online social activities and how we can leverage the relationships among different types of online social activities to improve the identification of influencers and the prediction of sales. We leverage a comprehensive dataset from an e-commerce platform where consumers can either purchase products directly or follow, like, or comment on the postings of influencers; the influencers may also directly interact with each other. We apply the Relational Graph Convolutional Networks method (R-GCN), which considers the multiplex nature of the networks, to address these tasks. Not only do these models improve the performance of prediction models based on single-layer network data, but they also yield important practical insights.

2 - From Self to Other: Customer Reactions to Firm DEI Promotions on Social Media

Chen Jing, Boston University, Boston, MA, United States, Priyanga Gunarathne, Shuba Srinivasan, Abraham Seidmann

Our paper investigates customer reactions to firm promotions of Diversity, Equity, and Inclusion (DEI) on social media. We assess how these initiatives affect customer communications, including complaints, and how perceptions vary across different demographic groups. Utilizing a dataset comprising public tweets from 15 major U.S. firms across various industries, collected from May 2020 to March 2023, we apply advanced Natural Language Processing (NLP) methods and face recognition technologies to classify DEI content and link it to specific customer identities. Through fixed-effects Poisson regression and the instrumental variables approach, our analysis reveals that DEI promotions are generally not well received by consumers, potentially exacerbating customer complaints even when paired with improvements in a firm's functional services. Our results also identify different impacts of DEI promotions based on their alignment with customer identities: promotions that coincide with customers' identities positively influence perceptions and reduce customer complaints. Additionally, we find that non-corresponding DEI promotions are the main source of adverse reactions, highlighting the critical need for alignment between DEI efforts and the distinct identities of customer segments. These insights underscore the nuanced challenges firms face in implementing DEI strategies that resonate positively across their diverse customer bases.

3 - Gender, Knowledge, and Engagement in Digital Communities of Practice: Evidence from X

Priyanga Gunarathne, University of Pittsburgh, Pittsburgh, PA, United States, Ruba Aljafari, Sezgin Ayabakan, Samer Khader, İbrahim Kulaç

Physicians are increasingly harnessing social media for professional networking, community interaction, and outreach. Unlike offline interactions within organizational hierarchies, where peers recognize each other's competencies and backgrounds, individual characteristics perceived on social media may shape online interactions, influencing career trajectories and peer recognition. Specifically, it remains unclear whether gender emerges as an individual characteristic influencing community engagement in digital physician communities on social media, as such online interactions involve nuances related to engagement with professional knowledge. Using the pathology community on X (formerly Twitter) as our research context, we exploit a novel dataset of professional conversations among pathologists on X and examine the role of gender in shaping peer engagement with professional knowledge. We leverage 2,467 patient case-based tweets posted by pathologists on X over a period of six months and employ a holistic set of tweet- and pathologist-specific controls and a matched sample approach as our empirical strategy. Our findings provide quantitative evidence of more favorable community engagement outcomes (likes, retweets, and replies) for professional knowledge created by female pathologists on X, compared to similar content created by similar male pathologists. To theoretically explore the identified gender differences, we surveyed pathologists on X. Our survey findings reveal that female pathologists are perceived as more communal, cooperative, and helpful, whereas male pathologists are viewed as more dominant and competitive. Our findings provide key insights for various stakeholders, including physicians, clinicians, hospital administrators, and platform owners who aim to foster, harness, and potentially to regulate communities of practice on digital platforms.

Community-Engaged and Equity-Forward Operations Research and Analytics II

Invited Session

Public Sector OR

Chair: Michael Johnson, University of Massachusetts Boston, Boston, MA, 02125, United States

1 - Simulation Optimization of Queueing Models for Capacity Planning in Homelessness Care Systems

Dashi Singham, Naval Postgraduate School, Monterey, CA, United States, Graham Burgess

A leading approach to resolving homelessness in highly populated areas is to increase the amount of housing and shelter available. Alameda County, located in the San Francisco Bay Area, has a focus on racial equity in its recent homeless response system redesign. By investing in multiple classes of housing to address different types of needs, Alameda County aims to address the unique needs of racial minorities who are overrepresented in the homeless population. We build a simulation models to assess the effects of investment levels in critical pathways designed to reduce the unsheltered population. Simulation optimization can be used to propose investment plans to best reach the housing goals of Alameda County's racial equity plan.

2 - Navigating Health Outcomes for Transgender Individuals: The Influence of State Legislation

Yuehwern Yih, Purdue University, West Lafayette, IN, United States, Min Kyung Lee

Addressing health disparities among transgender and gender-diverse (TGD) populations is a key public health concern. This study evaluates the dynamic causal relationships between state-level legislation and health outcomes for TGD individuals in the United States, employing a marginal structural model with inverse probability weighting to account for time-varying confounding, such as sociodemographic factors. We utilized data from the Behavioral Risk Factor Surveillance System (BRFSS) and the Human Rights Campaign's State Equality Index (HRC SEI), which provide comprehensive insights into health behaviors and legislative climates, respectively. Our findings indicate that discriminatory policies significantly exacerbate health disparities, leading to poorer mental and physical health outcomes among TGD populations. Notably, the interaction between legislation and transgender status significantly affects mental health, with unsupportive legislative environments intensifying negative impacts on both physical and general health for transgender respondents, whereas these legislative factors do not significantly impact the health outcomes of cisgender respondents. This study underscores the importance of supportive legislation in mitigating health disparities faced by TGD individuals and highlights the need for policies that promote health equity.

3 - Revisiting equity in urban operations management 50 years later: What do city planners have to say?

Mark Brennan, Rutgers University, Camden, NJ, United States

The persistent inequities in American cities—long recognized and lived by those disadvantaged by urban systems—have been vaulted into the broader public consciousness over the past decade. Lessening entrenched urban inequalities is now at the top of the national policy agenda, suggesting a need and opportunity for more urban operations management. On what issues and how might this work occur? Operations management was deeply intertwined with urban planning from the 1950s through the 1970s, at which point the fields diverged. To build a case for what perspectives a modern urban operations management agenda might employ to address inequity, I synthesize historical and current planning thinking with the debates among reflective urban operations scholars during 1950s-1970s. This urban operations agenda should be empirical, equity-oriented, and community-focused in order to resonate with city planners and the residents they serve. Modern operations scholars can look to new thinking in planning on race and class in order to address urban operations that especially disadvantage some city residents and overly advantage others. In reengaging with planners to tackle modern urban policy problems, operations analysts have a chance to contribute practical clarity on how cities work and can be made more livable for all.

Enhancing Supply Chain and Operations Efficiency: AI-driven Inventory Management

Invited Session

Artificial Intelligence

Chair: Zheng Zeng, Rutgers University, East Brunswick, NJ, United States

1 - A Queueing System with a Parallel Auxiliary Service

Peng Li, Rutgers Business School, Newark, NJ, United States, Chunliu Zhou, Lian Qi

This paper examines the maintenance and repair industry's practice of servicing high-value components of long-life-cycle machines. During machine servicing at primary stations, these components are removed and serviced at auxiliary stations, then reinstalled. To optimize machine utilization and minimize downtime, an inventory of fully serviced parts is maintained, allowing immediate swapping with depleted parts. We model this system as a queueing problem with primary and parallel auxiliary processes, focusing on optimal investment in primary and auxiliary servers and the inventory of backup parts, considering uncertainties in customer arrivals and service times. Our research uniquely optimizes investment in queueing systems with auxiliary servers and backup stocks. We establish the conditional probability of serviced part availability when customer demand exceeds primary server capacity and define stability conditions for the system. An approximation system is developed to provide near-optimal solutions with less than 5% numerical error, offering valuable managerial insights. This study contributes significantly to improving operational efficiency, service delivery, and customer satisfaction in maintenance and repair operations by optimizing resource allocation and management.

2 - Optimizing Production Capacity: Insights for Manufacturing Companies

Zheng Zeng, Rutgers University, Edison, NJ, United States, Xiaowei Xu

In the ever-changing market landscape, companies face the challenge of balancing customer demands for both immediate delivery and customizable products. In addressing the operational optimization challenges, this study adopts a robust methodology combining two-stage stochastic programming with the Newsvendor approximation.

The two-stage stochastic programming framework accommodates the inherent uncertainty in demand forecasting and production outcomes. In the first stage, decisions are made based on available information, such as prebuilt SKU inventory levels and production capacity. Assortment planning for top-selling SKUs is optimized to balance production constraints and demand variability, aiming to minimize costs while meeting customer requirements. In the second stage, which accounts for uncertainty, decisions are adjusted based on actual demand realizations. Here, the Newsvendor approximation is utilized to model the uncertain demand for immediate delivery and the potential for substitutions. The Newsvendor approximation helps to mitigate the risk of stockouts while minimizing excess inventory holding costs.

In addition, this study involved the practical application of the proposed approach using real-time data to facilitate a company's transition from a make-to-order to a make-to-stock model. The application of the methodology on real-time data allowed for a pilot implementation, providing the company with actionable insights and tangible results. By leveraging actual demand data, production capacity, and inventory levels, the study enabled the company to assess the feasibility and effectiveness of transitioning to a make-to-stock approach.

3 - Periodic Review Inventory Models with All-or-nothing Yield - A Transformer Framework

Zhe FU, City University of Hong Kong, Hong Kong, Hong Kong, Frank Chen

Training a deep reinforcement learning (DRL) model takes much time, including processes like storing computational graphs and computing gradients during forward and backward propagation. For inventory management problems, the states in Markov Decision Processes (MDP) typically include variables such as inventory levels, order quantities, and more. In many studies, the DRL agents utilize such states as input to take optimal actions like inventory adjustment strategies or orderings to maximize cumulative rewards. This paper proposes a novel approach to establish a pass-through connection between rewards and stochastic factors such as demands and random yields using Transformers, which is a class of deep neural networks (DNNs) with significant advantages in handling long-term dependencies and parallel processing. By integrating the MDP environment and DRL agents into Transformers’ architecture, our framework can process states that only contain random variables and directly output cumulative rewards. We utilize this framework with deep reinforcement learning to solve a single-item periodic review inventory problem with random demand, an all-or-nothing random yield pattern, and lead times. Its optimal structure is unknown, and the exact solution suffers from the curse of dimensionality. Our framework can handle these problems more efficiently and significantly improves computational speed compared to the general DRL models with inventory-related states. Moreover, this framework supports Transfer Learning, where the teacher's policies such as heuristic methods for the inventory problem are applied to train a model. Other applications of the proposed framework will also be discussed.

4 - SCGNN: Forecasting Food Prices with Constructed Supply Chain Graph and adopted Graph Neural Network Model

Fuqin Zhou, New Jersey Institute of Technology, Newark, NJ, United States, Jiaxing Zhang, Aichih Chang

The fluctuating prices of fresh food have created challenges for consumers and stakeholders after the pandemic. Existing methods treat the data as time sequences, which fail to measure the relationship between the markets and the impact of the supply chain network. To address this issue, we need a predictive model that can forecast prices on a large scale, taking into account factors such as spatial origins, transportation networks, terminal markets, and food categories. In our study, we gathered a spatial-temporal dataset of fresh food prices in US markets. We adopted a spatial-temporal Graph Neural Network (ST-GNN) framework to create a comprehensive solution for various forecasting tasks, including a gated message-passing mechanism to capture the inherent interdependencies in food prices. Our solutions aim to contribute to stability and resilience in the agricultural food market ecosystem.

Value Creation in Online Platforms

Contributed Session

Chair: Prabin Panigrahi, Indian Institute of Management Indore, Indore, India

1 - Rebate policies in the presence of social learning and strategic consumers

Bingyue Hu, Tianjin University, Tianjin, China, People's Republic of, Yuan Chen, Yinghua Shen

With the prevalence of online shopping, firms have recognized the influential role of online reviews in shaping consumers' beliefs about product quality. To capitalize on this, firms have employed rebate strategies incentivizing consumers to write reviews and even positive reviews. Note however, with the increasing rebate amount of firms, consumers may anticipate potential benefits of using more generated reviews to reduce their uncertainty of product quality, leading more consumers strategically delay their purchasing decisions. This dilemma makes it unclear for firms to determine right rebate policies. This paper employs a game theoretical model to investigate the interaction between firms and strategic consumers within the framework of Social Learning (SL), where consumers update their beliefs about product quality through Bayesian rule after observing reviews from previous purchasers. We develop a two-period stylized model to analyze sellers' pricing and rebate strategies (conditioned on writing reviews or positive reviews), considering the strategic decisions of consumers on when to purchase and whether to write reviews. Our research reveals that rebate policies are beneficial since SL is advantageous for both consumers and firms when there is no information distortion or only slight information distortion. This environment facilitates well-informed purchase decisions for consumers, while firms gain a better understanding of consumers' product quality beliefs. However, we also examine how the extent of information distortion affects firm profit and consumer surplus. Our findings indicate that information distortion invariably benefits firm profit and detrimentally impacts consumer welfare; but this happens only when penalty of review manipulation is low.

2 - Fast solution to the fair ranking problem using the Sinkhorn algorithm

Yuki Uehara, University of Tsukuba, Tsukuba-shi, Japan, Shunnosuke Ikeda, Naoki Nishimura, Noriyoshi Sukegawa, Yuichi Takano

Ranking algorithms play an important role in e-commerce recommendation systems. Traditional rankings focused only on buyer satisfaction, but recently it has become increasingly important to consider the satisfaction of item providers. Rankings that aim to fairly increase the satisfaction level of item providers are called fair rankings. The fair ranking problem for leveling the expected impact on each item is formulated as a large-scale constrained nonlinear optimization problem, but it is time-consuming to solve this problem using commercial optimization solvers. To efficiently solve the fair ranking problem, we propose a gradient ascent method that is highly compatible with parallel processing. To this end, we reformulate the problem as an unconstrained problem involving a projection function, which is implemented by the Sinkhorn algorithm in our method. The Sinkhorn algorithm is suitable for parallel processing and provides gradient information for the reformulated problem. Numerical results demonstrate that our method is significantly faster than applying a commercial optimization solver to the existing formulation, without compromising solution accuracy.

3 - Fake Reviews are out of Depth: Fake Review Detection using Semantic Networks.

Prabin Kumar Panigrahi, Indian Institute of Management Indore, Indore, India, Abhishek Kumar Jha

In the digital age, online consumer reviews (OCRs) significantly influence purchasing decisions, making platforms vulnerable to fake reviews. This study aims to improve fake review detection by analyzing the semantic differences between fake and real reviews using network text analysis. The research first identifies these differences in an uncontrolled eCommerce environment. Reviews from Amazon were pre-processed and analyzed, with each review represented as a network node connected by edges based on cosine similarity. Network properties such as density, connected components, and clustering coefficients were evaluated to distinguish fake from real reviews. Incorporating these network-derived parameters into machine-learning models significantly improved detection accuracy. The findings reveal that fake reviews exhibit higher semantic similarity within product categories, enhancing model accuracy for identifying fake reviews, among others. This novel approach provides both theoretical insights about the characteristics and practical tools for better managing the authenticity of online reviews, contributing to a more trustworthy eCommerce environment. The underlying findings also indicated in the conversation that the reviews, when real, are more specific, leading to a lower similarity.

In contrast, the fake review only repeats the conversation about the highlighted product features without more variation. This is a theoretical finding that we believe is true for another form of misinformation across different networks. Limitations include the use of cosine similarity and testing on local networks, suggesting future research could explore alternative measures and broader network scopes.

Keywords: Fake Review, Semantic Network, Network Analytics, Machine learning

Innovations in AI and Digital Engagement

Contributed Session

Chair: Manni Gao, Harbin Institute of Technology, Harbin, N/A

1 - Discovering Convergence of AI Technology and their Spreads: Network Perspectives

Won Sang Lee, Gangneung Wonju National University, Gangneung, Korea, Republic of

Currently, the convergences with AI technology accelerate diverse interactions and continuous advancements in many areas, thereby attracting great interests of both researchers and practitioners. Such technological convergences on AI and their spreads unprecedently occur in the complicated phases. The necessity of comprehensively investigation is increasing. This paper focuses on what technologies have been composing AI convergences and how those spread into diverse domains based on the entire triadic patents. The network dynamics and diffusion model are jointly deployed to track such spreads of AI with emphasis on the impact of the technological convergences of AI. In particular, it is further concerned whether these convergences benefit from the inflow of external technology or affect other technologies during the spread of AI convergences. The proposed methodology is expected to discover the promising AI convergences. Findings of this paper could, then, lead us to acknowledge the intrinsic nature of AI convergences and provide the policy implication for their utilization and dissemination.

2 - Does content matter? The influence of fine-grained, textual aspects on review helpfulness.

Alexander Kupfer, University of Innsbruck, Innsbruck, Austria, Stefanie Erlebach, Kilian Züllig, Leonie Embacher, Steffen Zimmermann

Even though helpfulness votes in online review systems predominantly aim to facilitate the consumers' identification of the most helpful opinions on a product (Mudambi and Schuff, 2010), the consequential data availability of online consumer reviews that are voted as helpful has also attracted many scholars in Information Systems research. Many studies use these votes as dependent variables to examine the relevance of various factors that "make" a review helpful (see Rietsche et al., 2019, for an overview). The use of these votes, however, restricts the analysis' effectiveness in terms of granularity, and one consequently observes rather "broad" metrics like, for instance, textual length or overall sentiment to be correlated with helpfulness votes. Even though one would expect that the actual content of a review influences its helpfulness, there is no evidence on how fine-grained, textual aspects affect review helpfulness. To address this lack of knowledge, we used a real-world review dataset, classified the respective reviews textual content along four dimensions (product-related, customer-related, seller-related, and purchase condition-related) including the dimensions' sentiment, and applied a discrete choice experiment to extract fine-grained helpfulness preferences. In this context, we transfer the feature of discrete choice experiments to extract preferences for specific product characteristics to identify preferences for specific textual characteristics in reviews. Our preliminary findings indicate that – as expected – particularly product-related aspects (positive and negative) are helpful. However, we also document that, e.g., purchase condition-related aspects are not helpful. Having fine-grained information about review helpfulness is essential for academics and businesses alike.

3 - Loyal Costumer, Brand Defender or Betrayer? Evidence From Sequential Scandals in Multi-Brand Apparel Firms

Yi Zeng, City University of Hong Kong, Hong Kong, China, People's Republic of

Brand scandals have always been an interesting and commercially valuable research topic. After a scandal, consumers change their attitudes towards the brand and their purchasing behavior, which in turn affects brand equity and profitability. Previous research has shown that consumers with different characteristics will react differently to the same scandal, and understanding the differences and underlying mechanisms can help brands apply different strategies to different groups when it comes to remediation.

By using the DID model, we analyzed the types of consumers and their purchasing data before and after two consecutive scandals in a Chinese multi-brand clothing company and conducted a robustness test. Preliminary results suggest that loyal consumers are more likely to reduce consumption and disassociate from brands when faced with value-related scandals. We also find that this effect is influenced by consumers' attribution: when the scandal of sub-brand is attributed to the parent brand, the parent brand not only suffers negative spillover effect, but also the betrayal extent of its loyal customers is greater; When the sub-brand scandal is attributed to itself, the parent brand's loyal customers appear to defend and the sub-brand's loyal customers appear to betray. In addition, combined with the text analysis of the related posts on Weibo, we also found the influence of social media in the fermentation of the scandal.

4 - Specialization or Diversification? Creators' Strategies and User Engagement in User-Generated Content (UGC) Platforms

Ziwei Ye, Old Dominion University, Norfolk, VA, United States, Kedong Chen, Lan Cao

Recent advancements in social media have revolutionized content creation and distribution. User Generated Content (UGC), consisting of original content created and shared by internet users, is reshaping the realms of entertainment, communication, and information. To maintain a competitive advantage, UGC creators may strategically adopt specialization or diversification in their content creation. Specialization refers to a focus on "only one type of task" (e.g., a specific niche, topic, or content category within the platform), whereas diversification engages in multiple tasks, seeking to capitalize on the competitive advantages of being a "one-stop shop" by offering a diverse range of products and services. While prior studies have examined the impact of specialization degrees on creators' follower growth, the existing literature offers limited evidence on how such strategies either enhance or diminish user engagement. This study leverages a substantial panel dataset from a popular short video platform to examine how creators' specialization versus diversification strategies affect user acquisition and retention. Employing fixed effects models, we find that the degree of creators' specialization is positively associated with their user acquisition rate while negatively associated with their user retention rate. Furthermore, the effect of creators' specialization strategy on user engagement is moderated by platform's algorithmic intervention. These findings underscore the trade-off between specialized and diversified content strategies in shaping user engagement metrics. By understanding these dynamics, platforms can better guide creators in selecting strategies that optimally balance user acquisition and retention, thereby maximizing overall user engagement.

5 - Empowering Innovation: An Empirical Study on the Impact of Generative AIon Online Freelancers' Performance

Manni Gao, Harbin institute of Technology, Harbin, China, People's Republic of, Jianwei Liu, Qiang Ye

Generative AI is revolutionizing content generation, particularly redefining success for freelancers engaged in image creation. This study examines the impact of generative AI adoption on freelancers' performance and dissects the underlying mechanisms. Leveraging extensive data from freelancers specializing in image creation on a premier global gig economy platform, we adopt a difference-in-differences methodology for empirical analysis and use deep learning techniques to assess specific image attributes, such as color and content diversity. We have three main findings. First, adopting generative AI improves freelancers' performance in color and content diversity of their generated images while also expanding their order volumes and customer reach. Second, the mechanism centers on the limited lifting effect of generative AI on human-generated images, which notably increases order volumes and content diversity without altering the fundamental styles, except for those with relatively singular painting styles. Third, content diversity empowered by generative AI is a strong driver of growth in traditional manual services, but the reason behind overall services growth is relatively mixed. Our research contributes to two critical areas: (1) the examination of technological evolution's impact on online labor markets, an area underexplored in existing literature, and (2) the implications of generative AI on content creation, where this emerging technology is reshaping creative paradigms. This research provides insights for administrators and policymakers on adapting to the emerging technology and making informed decisions.

E-commerce and Supply Chain Management

Invited Session

eBusiness

Chair: Emily Griffin, Babson College, Wellesley, MA, United States

1 - Online Supplier Selection

Thomas Cassidey, Cal State, East Bay, Hayward, CA, United States, Emily Griffin, Burcu Keskin

We address the problem of an e-retailer that connects drop shipping suppliers to customers. The retailer must balance the potential tradeoffs between cost and delivery performance on each order. We develop and compare several algorithms to manage this tradeoff and present empirical results.

2 - Bargaining Over Data and Analytics: Sellers, Buyers and Consultants

Jyotishka Ray, University of Dayton, Dayton, OH, United States

The explosive growth of online commerce has generated large quantities of data that can be used by firms to improve decision making. Some of the data collected can be directly used by firms, for example, in an advertising campaign to target certain users. In other cases, these data sets can be further analyzed using sophisticated analytic methods to substantially increase their value.
We examine the selling of data where the value to the data buyer can be enhanced with the use of analytic services obtained from a consultant. Because our context emphasizes the exclusive selling of proprietary and unique data (rather than general purpose data that can be sold to many buyers), announcing a fixed price for the data is not a viable option for the seller. Thus we use a Nash bargaining framework where the negotiations always involve the data seller and buyer and could sometimes involve a consultant. Data sellers can choose to sell the data alone or sell a bundle that includes the data and complementary analytic services. Data buyers can choose to simultaneously negotiate the price of data and the price of analytic services. Alternatively the data buyer could perform these negotiations in two separate steps. Our analysis shows that the contribution of the consultant's analytic services is critical to both the seller's decision to bundle and the buyer's choice over how best to structure the negotiations. Data sellers have a natural advantage over external consultants when they choose to bundle data with complementary analytic services.

3 - How many software versions to support: The role of software support experience & cost

Jayarajan Samuel, The University of Texas at Arlington, Arlington, TX, United States, Alper Nakkas

Commercial off the shelf (COTS) software form the backbone of any e-business platform. The product support of these COTS software products is a profitable and cost sensitive business. We investigate, though a unique dataset, the effect of software versions on user support experience and costs. We find that keeping customer software deployments in homogenous software versions is challenging but has high rewards. We further draw causal insights on the effects of divergent software release deployments on cost.

4 - Return Freight Insurance Strategy in Competitive E-Commerce Operations

Shan LI, Shanghai Jiao Tong University, Shanghai, China, People's Republic of

In response to consumers' pursuit of free return shipping, Chinese e-commerce platforms provide free return insurance to consumers. Meanwhile, with the increasing encroachment of platform-operated e-tailer in the market and its emergence as competitors to the manufacturer in the downstream supply chain, a crucial question arises: when should firms provide free return freight insurance (RFI) to consumers in this new environment? Our research reveals that offering RFI leads to an increase in demand for the firm and a decrease in demand for rival firms, which we term the *market expansion effect* caused by RFI. We also find that manufacturers are more motivated to offer RFI compared to platform-operated e-tailers. Additionally, both of these two firms tend to set a higher retail price when they provide RFI to consumers, regardless of the insurance premium's value. This phenomenon, which we refer to as the *cost enhancement effect*. Furthermore, we find that when the insurance premium is low, both of these two firms would provide return freight insurance. However, as the premium increases, neither party would offer return freight insurance to consumers. Interestingly, in cases where the insurance premium is high and the rival firm does not offer RFI, both firms surprisingly benefit from the decision to provide RFI. This is due to the significant *market expansion effect* experienced by the firm offering RFI under this circumstance, resulting in benefits for the e-tailer even with a sufficiently large premium. We term this phenomenon the *mutual exclusive effect*.

Advances in Sustainable Energy Systems Operations

Invited Session

ENRE: Electricity

Chair: Kai Pan, The Hong Kong Polytechnic University, Hung Hom, Hong Kong

Co-Chair: Bin Tian, N/A

1 - Operationalizing Smart Charging; a Robust Optimization Interpretation of Flexibility Vs Uncertainty

Linda Punt, Rotterdam School of Management, Rotterdam, Netherlands, Yashar Ghiassi, Gar Goei Loke

The electrification of transportation and increasing electric vehicle (EV) adoption poses challenges for local power grid management. Our research addresses these challenges by (i) proposing a decision-support model in the form of a robust optimization framework for implementing different smart charging regimes, and (ii) analyzing the interplay between uncertainty and flexibility in smart charging. Specifically, we propose an aggregate model for EV arrivals and departures and prove that individual EV charging schedules can be recovered from their solutions. We also propose a novel uncertainty set that incorporates length of stay (LOS) to relate EV arrivals and departures. Through our model, we offer insights into various flexibility options, revealing that smart charging, even when LOS is exogenously determined, can prove more cost-effective than no smart charging for sufficiently high rates of EV adoption. We also emphasize the importance of optimal external grid capacity and battery investments, showcasing their complementary relationship with EV adoption rates under smart charging, and note that increased investments in these complementary flexibility instruments enhance the cost-effectiveness of implementing smart charging for operators. Additionally, our analysis identifies batteries as the most cost-effective solution to mitigate EV departure uncertainty.

2 - Charging An Electric Vehicle on Fast-Lane and Station: Convenience, Accessibility and Availability

Yanlu Zhao, Duham University Business School, Durham, United Kingdom, Kai Pan

The rapid increase in electric vehicle (EV) use has profoundly transformed urban transportation and placed significant demands on the energy system, primarily due to the increased need for battery charging. Stationary charging limits vehicle availability, particularly for heavy goods vehicles (HGVs) that require substantial energy for long-haul trips with heavy loads. This requirement adds to the vehicle weight, perpetuating a problematic cycle. In response, some pioneering countries like Sweden and innovative companies are exploring road-charging technologies that charge EVs while they are moving, thus reducing downtime for charging and bringing this strategy into the spotlight. Our research focuses on this innovative charging approach by examining a new problem that integrates both road and stationary charging methods. We utilize mixed-integer programming to address this issue and broaden our investigation to account for uncertainties in charging station availability and variable energy prices. We adopt a distributionally robust approach to develop broader strategies for more practical contexts. The effectiveness of our solutions is validated using real data from China, demonstrating the significant benefits from mixed charging strategies. We also obtained more managerial insights that guides the charging station design and energy budget management.

3 - A Polyhedral Study on Unit Commitment with A Single Type of Binary Variables

Bin Tian, The Hong Kong Polytechnic University, KOWLOON, Hong Kong, Kai Pan, Chung-Lun Li

Efficient power production scheduling is a crucial concern for power system operators aiming to minimize operational costs. Previous mixed-integer linear programming formulations for unit commitment (UC) problems have primarily used two or three types of binary variables. The investigation of strong formulations with a single type of binary variables has been limited, as it is believed to be challenging to derive strong valid inequalities using fewer binary variables, and the reduction of number of binary variables is often accompanied by a compromise in tightness. To address these issues, this paper considers a formulation for unit commitment using a single type of binary variables and develops strong valid inequality families to enhance the tightness of the formulation. Conditions under which these strong valid inequalities serve as facet-defining inequalities for the single-generator UC polytope are provided. For those large-size valid inequality families, the existence of efficient separation algorithms for determining the most violated inequalities is also discussed. The effectiveness of the proposed single-binary formulation and strong valid inequalities is demonstrated through computational experiments on network-constrained UC problems. The results indicate that the strong valid inequalities presented in this paper are effective in solving UC problems and can also be applied to UC formulations that contain more than one type of binary variables.

4 - Decarbonizing Mining Operations: Co-Optimization Strategies for Clean Energy Integration and Operations Planning

Vivienne Liu, National Renewable Energy Laboratory , Golden, CO, United States, Thomas Jeffery, Sourabh Dalvi, Gord Stephen, Devon Sigler

Mining is among the most energy-intensive activities in industry, and a notable remaining challenge in transitioning to fully decarbonized energy systems. This work develops a co-optimization model to plan and operate a fully decarbonized iron ore mining operation, by electrifying diesel-powered mining vehicles to enable them to run on clean electricity resources such as wind, solar, and battery storage. A significant portion of the mining system's electricity consumption stems from mining trucks and processing facility operations, offering substantial demand-side flexibility provided by responsive EV charging and ore processing schedules. Moreover, the stockpiles for mining products provide extra energy storage options and serve as a buffer during extreme events. Therefore, coordinated planning and operation of mining facilities and the power system are vital for cost-effectively achieving decarbonization goals in the mining sector.

In collaboration with Fortescue, we develop a co-optimization model that incorporates mining operation constraints for use with power system production cost model. The results showcase viable strategies to reach clean energy targets and offer insights into facility expansions for both mining operations and renewable energy integration.

5 - Hybrid Quantum Classical Computing for Energy System Management

Lei Fan, University of Houston, Houston, TX, United States, Zhongqi Zhao, Zhu Han

In this talk, we will discuss how to utilize the hybrid quantum classical computing techniques to solve the energy management challenges. We will introduce the hybrid quantum classical Benders' decomposition algorithms and its application in energy management system. We will show the simulation results to verify the our proposed algorithm and the advantages of the quantum computing on the cloud.

Integration of Human, Knowledge and Systems for Quality

Invited Session

Data Mining

Chair: Feng Lin, University of Washington, Mountlake Terrace, WA, United States

1 - Trust-aware Human Robot Interaction in Manufacturing Plant

Jundi Liu, Iowa State University, Ames, IA, United States, Mobina Amorollahi, Rindirisia Wangira

Large industrial robots are a cornerstone in contemporary manufacturing, undertaking tasks that demand heavy manual effort or monotonous repetition. Among these, Automated Guided Vehicles (AGVs) have been deployed in numerous manufacturing settings, streamlining the transportation of parts for subsequent processing or operations. Despite their prevalence, these vehicles typically operate in isolated zones, separate from human workers. This segregation stems from two primary concerns: firstly, there's a notable lack of trust among workers towards these mobile robots within safety-critical environments, which hinders the adoption of such systems; secondly, the uncertain nature of human behavior introduces variables that current AGVs struggle to accommodate. Current research often treats human as a data generator and builds data-driven models that lack theoretical understanding of how cognition guides the behaviors. In this study, we utilized Virtual Reality (VR) to create a simulated manufacturing environment to collect data on human behavior while interacting with AGVs. We then analyzed this behavioral data and developed a trust prediction model based on these behaviors to address the inaccuracies often found in self-reported trust measures. This trust prediction model has significant implications for the design of future trust-aware adaptive systems, ultimately enhancing human-robot interaction.

2 - Quality Control in Crowdsourcing based on Random Utility Modeling

Hanming Zheng, City University of Hong Kong, Hong Kong, Hong Kong, Shuai Huang, Li Zeng

Crowdsourcing has emerged as a popular way to conduct complex tasks by combining the contributions of a large group of workers. One challenge in crowdsourcing is quality control, i.e., aggregating the outputs of workers considering worker variations to ensure reliable crowdsourcing results. Some quality control methods have been developed in recent years for certain type of tasks such as binary labelling, but there lacks a generic approach that works for various tasks. This study proposes a novel, simple statistical framework for quality control in crowdsourcing to address the research gap. The proposed method is based on a random utility modelling (RUM) of worker outputs and affecting factors such as worker ability and task difficulty level. Based on the model, subgroups of high-quality workers who will be relied on to generate final result for the given task are further identified via density-based clustering. Although illustrated using binary labelling tasks in this study, this method also applies for other types of crowdsourcing tasks including multi-category labelling, rating, etc., thanks to the generality of RUM. The case study shows that this method is robust across different scenarios and especially it outperforms existing methods when worker assignment is sparse.

3 - Modeling dynamic disease-behavior feedbacks for improved epidemic prediction and response

Hongru Du, Johns Hopkins University, Baltimore, MD, United States, Lauren Gardner, Alison Hill, Sara Loo, Nicholas Papageorge, Bryan Patenaude, Shaun Truelove, Mattew Zahn

Infectious disease transmission and control are deeply intertwined with human behavior. Traditional epidemiological models, while valuable, often overlook the complex decisions individuals make in response to changing disease risks and policies. This study introduces a novel framework that integrates individual decision-making with disease transmission dynamics. By incorporating feedback loops, externalities, and diverse decision-making processes, our model offers a more comprehensive understanding of the interplay between behavior, disease spread, and policy interventions. We demonstrate the capability of this framework by examining how individual decisions influence disease transmission and the subsequent impact of policy choices on health outcomes and work participation in scenarios mirroring COVID-19-like outbreaks. This approach allows us to assess not only epidemiological outcomes but also the economic costs and welfare implications of interventions, particularly for diverse sub-populations with varying health and economic vulnerabilities. Our findings emphasize the crucial role of considering endogenous behavioral responses in policy design. They highlight the potential for more targeted, equitable interventions that effectively balance public health objectives with individual well-being. By integrating human behavior into epidemiological models, we pave the way for more effective and nuanced strategies to combat infectious diseases.

4 - A Rawlsian Mixed Integer Programming Approach for Fair Classification

William Yang, Lawrence Livermore National Lab, Livermore, CA, United States, Chaoyue Zhao, Shuai Huang, Ryan Lin

Traditional binary classification algorithms are prone to producing unfair results that favor certain demographic groups over others. This inequity is often exacerbated in unbalanced datasets where the number of entries from a majority group significantly outweighs the entries from a minority group. We use a mixed-integer-programming (MIP) framework to formulate our Rawlsian fairness methohdology to address these inequities. Our methodology prioritizes the performance of the worst-off demographic group, and our specific formulation can produce interpretable solutions by directly optimizing sparsity. Additionally, it provides flexibility for users to achieve interpretable solutions in multiple ways.

We directly optimize accuracy and sparsity while providing model flexibility that enhances interpretability by allowing the user to adjust sparsity through penalization in the objective or with upper-bounding constraints. We also offer flexibility to obtain real or integer coefficients based on domain-based preferences. Furthermore, our model outputs a single optimal threshold, which alleviates the user from selecting a threshold value before implementing the model. Consequently, our model provides deterministic classification results instead of probability values assigned to each individual.

Our experimental results display our Rawlsian MIP's ability to prioritize the performance of the worst-off group while still maintaining a high classification accuracy overall, even when performed on an unbalanced dataset. We also showcase the flexibility of our method in its ability to adjust the sparsity and interpretability of the results. Lastly, we compare our results to other fairness metrics, and discuss our method's differences with respect to other Rawlsian classification methods.

5 - Mixture-of-Experts Modeling with Shape Constraints and Its Application to Materials and Industrial Systems

Yating Fang, Rutgers University, Industrial & Systems Engineering, Piscataway, NJ, United States, Qianqian Zhao, Ryan Sills, Ahmed Aziz Ezzat

Shape constraints, such as monotonicity, arise in many engineering and scientific applications, as motivated by some underlying physics or existing theory. We are interested in the problem of imposing monotonicity constraints in the context of mixture-of-experts (MoE) modeling – where multiple machine learning models (referred to as experts) are trained on different data subsets, and then merged -using internally estimated input-dependent weights (referred to as gates)- to produce a combined mixture model. The main motivation of MoE is to accommodate data heterogeneity arising from distinct physics-based regimes, and/or reduce computational cost of training large machine learning models. Unfortunately, the resulting mixture is not guaranteed to be monotone, even if the constituting experts are, limiting MoE's applicability to several scientific and engineering applications where monotonicity is desirable, if not necessary. In response, we propose novel variations to the MoE framework in order to enforce monotonicity on the resulting mixture, without sacrificing its predictive power. Our proposed method is shown to perform well on simulated datasets, as well as on real-world datasets from materials/industrial systems experiencing multi-physics regimes.

Optimization and Surrogate Methods for Black-Box Systems

Invited Session

Data Mining

Chair: Nazanin Nezami, University of Illinois Chicago, Chicago, IL, United States

Co-Chair: Hadis Anahideh, University of Illinois Chicago, Chicago, IL, United States

1 - Building Trust in Black-box Optimization: A Comprehensive Framework for Explainability

Nazanin Nezami, University of Illinois Chicago, Chicago, IL, United States

Optimizing costly black-box functions within a constrained evaluation budget presents significant challenges in many real-world applications. Surrogate Optimization (SO) is a common resolution, yet its proprietary nature introduced by the complexity of surrogate models and the sampling core (e.g., acquisition functions) often leads to a lack of explainability and transparency. While existing literature has primarily concentrated on enhancing convergence to global optima, the practical interpretation of newly proposed strategies remains underexplored, especially in batch evaluation settings. We propose Inclusive Explainability Metrics for Surrogate Optimization (IEMSO), a comprehensive set of model-agnostic metrics designed to enhance the transparency, trustworthiness, and explainability of the SO approaches. Through these metrics, we provide both intermediate and post-hoc explanations to practitioners before and after performing expensive evaluations to gain trust. We consider four primary categories of metrics, each targeting a specific aspect of the SO process: Sampling Core Metrics, Batch Properties Metrics, Optimization Process Metrics, and Feature Importance. Our experimental evaluations demonstrate the significant potential of the proposed metrics across different benchmarks.

2 - Bayesian Optimization for Inverse Problems with Intractable Likelihoods

Peter Frazier, Cornell / Uber, Ithaca, NY, United States

We consider calculation of the posterior density over uncertain parameters when the forward model is time-consuming to evaluate. This problem arises, for example, in epidemic modeling, where we wish to estimate parameters in an epidemic simulation by comparing its predictions to observed data, and where each simulation requires significant computation.

Bayesian optimization of composite functions (Astudillo & Frazier 2019) provides an efficient way to maximize the posterior density: use a Gaussian process to predict the output of the forward model at unseen parameter values; use knowledge of the likelihood and the prior to predict the unnormalized posterior; and use a classical acquisition function to choose the next point at which to evaluate the forward model. While quite efficient, this approach is limited to providing point estimates of the uncertain parameters.

We show how a significant generalization of these ideas supports approximate fully Bayesian inference over the uncertain parameters. By using a compositional Gaussian process model and an acquisiton function designed to prioritize localization of areas where the likelihood is high, we can draw samples from a high-quality approximate posterior with a small number of forward model evaluations. We illustrate these ideas with examples from epidemic modeling and climate-responsive plant breeding.

3 - Simulation Optimization with Non-Stationary Streaming Input Data

Haowei Wang, National University of Singapore, Singapore, Singapore, Songhao Wang, Szu Hui Ng

Simulation optimization has become an emerging tool to design and analysis of real-world systems. In stochastic simulation, input distribution is a main driving force to account for system randomness. Most existing works on input modeling focus on stationary input distributions. In reality, however, input distributions could experience sudden disruptive changes due to external factors. In this work, we consider input modeling through non-stationary streaming input data, where the input data arrive sequentially across different decision stages. Both the parameters of the input distributions and the disruptive change points are unknown. We use a Markov Switching Model to estimate the non-stationary input distributions, and design a surrogate based approach to solve the following optimization problem. The proposed surrogate and optimization algorithm can utilize the simulation results from all the past stages. A numerical study on an inventory system shows that our algorithm can solve the problem more efficiently compared to common approaches.

4 - Clustering Simulation Output Distributions for pre-optimization and online monitoring

Mohammadmahdi Ghasemloo, Texas A&M University, College Station, TX, United States, David Eckman

Analyzing simulation outputs using statistical learning methods can improve decision-making by exploring relationships between simulation inputs and outputs in preparation for optimization. We focus on the task of clustering multivariate distributions of simulation outputs to identify patterns and tradeoffs and to better understand the behavior of a system. We introduce a novel agglomerative clustering algorithm that leverages the regularized Wasserstein distance to group system configurations having similar output distributions. We explore several use cases for this framework, including anomaly detection and pre-optimization. In numerical experiments of a simulated call center, we apply the proposed methodology to identify staffing plans that achieve similar performance and to develop policies for intervening when the queue lengths indicate that system performance is at risk of sharply deteriorating.

Advances in Machine Learning and Decision Analytics

Invited Session

Data Mining

Chair: Shouyi Wang, The University of Texas at Arlington, Arlington, TX, 76019, United States

Co-Chair: Dervis Ozay, The University of Texas at Arlington, Arlington, TX, 76155, United States

1 - Does YouTube affect medical decision making? Causal machine learning for health disparities

Minh Nguyen, Michigan State University, East Lansing, MI, United States

Understanding causal relationships is crucial for making decisions, especially in some critical fields like health care. In these critical fields, understanding associative relationships might not be enough. This work focuses on estimating causal effects of accessing YouTube (or Dr.YouTube) on medical decision making. In order to do this, we employ a list of traditional econometric as well as current advanced causal machine learning methods for treatment effect estimation. We utilize the Health Information National Trends Survey (HINTS), which is a reliable data set of the American public’s knowledge of health-related information. The results show that Dr. YouTube consistently positively impacts medical decision making of the individuals. This result is robust under different refute tests. Moreover, we go beyond general causal results by investigating and providing new causal understanding on health disparities. This work implies that YouTube is not just a source for accessing medical information as the existing literature but also the one for medical decision making.

2 - Treatment Response Prediction of Lung Cancer Using Deep Learning

Shouyi Wang, The University of Texas at Arlington, Arlington, TX, United States

In this presentation, we explore the revolutionary capabilities of deep learning in predicting treatment responses for lung cancer patients. Utilizing a comprehensive dataset comprising clinical features, genomic data, and imaging studies, we developed a robust deep learning framework capable of assessing patient-specific treatment outcomes. Our model integrates convolutional neural networks (CNNs) for image analysis and recurrent neural networks (RNNs) for sequential data processing, achieving a significant predictive accuracy compared to traditional statistical methods. We also address the challenges of model interpretability and data heterogeneity, implementing techniques such as layer-wise relevance propagation to elucidate decision-making processes. The results demonstrate the potential of deep learning to personalize therapy plans, thus improving survival rates and quality of life for lung cancer patients. This talk will detail the methodologies, results, and future directions of our research in transforming oncological treatment paradigms.

3 - Improving Binary Classification Performance under Class Imbalance via Minority Sub-Classes

Tai-Jung Chen, Virginia Tech, Blacksburg, VA, United States, Kwokleung Tsui

Many real-world classification tasks are highly class imbalance. This results in the machine learning classifiers performing poorly on the minority class samples although performing well within the majority class samples. Given the sub-class information within the minority class, we found out local models, which are trained on majority class samples and each minority sub-class samples respectively, had higher precision and specificity due to lower false positive classifications. We propose DNC, (Divide aNd Conquer), a method that utilizing the minority sub-class information to divide the imbalance binary classification problem into several sub-problems, conquer each sub-problem via local models one by one, and aggregate the classifications from the local models to enhance the performance of the original imbalance binary classification. We showed that DNC can improve precision comparing to using the conventional binary classification method. While

DNC and One-versus-One (OvO) have similar performance, DNC is more time efficient and can reduce the number of classifiers trained from k chose 2 to $k - 1$ (where k is the number of classes)*, due to the design of training fewer local models.*

4 - Randomization Against Non-Stationarity: A Best Arm Identification Algorithm for Smart Healthcare

Yanwen Li, Nanyang Technological University, Singapore, Singapore, Zhenzhen Yan, Guangyan Gan

Policymakers for public healthcare services seek the strategy with the maximum prevention effectiveness of an infectious disease (e.g., HIV, COVID-19) among a set of prevention strategies. Clinical and simulation studies are the primary experimental methods to evaluate the effectiveness of prevention strategies, whereas the inherent non-stationarity (e.g., distributional shift) of the unpredictable bias between the experimental effectiveness and the true effectiveness of each strategy may cause non-negligible interference in the effectiveness evaluation and policy-making. In addition, limited experimental resources urge policymakers to improve the quality of experimental design and policy-making. This gives rise to a pressing need for an efficient resource allocation algorithm to properly evaluate each strategy and correctly identify the strategy with maximum effectiveness. We formulate the problem of disease prevention in homogeneous populations as a best arm identification problem in non-stationary stochastic environments, focusing on a fixed-budget scenario, where the strategies can be evaluated over a fixed number of rounds. Specifically, the quantitative results of the experimental effectiveness of each strategy are distorted versions of its true effectiveness, with the distortion process unbeknownst to policymakers. The goal is to design an allocation algorithm that maximizes the asymptotic decay rate of the probability of incorrect identification. To provide a systematic way of experimental design and policy-making, we apply the combination regimen of the large deviations theory and an adaptive randomization scheme to quantify a worthwhile tradeoff of resource allocation between effectively evaluating prevention strategies and actively defending against non-stationarity. Numerical results show the efficiency of our randomized algorithm.

Energy Systems Integration

Invited Session

ENRE: Energy-Climate

Chair: Dharik Mallapragada, MIT Energy Initiative, Massachusetts Institute of Technology, 5 Metrotech Center, Cambridge, MA, 11201, United States

1 - Energy Transition Planning Using Stochastic Programming and a Control-Inspired Approach

Molly McDonald, Princeton University, Princeton, NJ, United States, Christos Maravelias

Energy system models can facilitate our understanding of how investment choices today can affect the ability to meet desired goals, such as reaching net zero emissions while still satisfying energy demand. However, although energy system models have been useful in demonstrating the potential impact of climate policy, most such models have two key limitations: 1) they are based on the assumption that the values of key parameters throughout the time horizon are deterministically known*;* and 2) decisions over the full planning horizon, which may be decades, are made at a single point in time at the beginning of the horizon. We propose different methods to address these limitations and thereby better represent the decision-making process in the presence of uncertainty. We use multistage stochastic programming (MSSP) to account for uncertainty in key parameters, such as future energy demands. We pair this method with a sequential decision-making approach that better represents the ability of a decision-maker to update decisions as uncertainties unfold. We then apply a simulation-based framework to evaluate the quality of the energy transition pathways that are developed by the proposed methods. We find that accounting for uncertainty with MSSP and having the ability to react to uncertainty with the sequential decision-making approach leads to more diverse energy transition pathways that are less sensitive to uncertainties in key parameters.

2 - Locational Marginal Pricing of Energy in Pipeline Transport of Natural Gas and Hydrogen with Carbon Offset Incentives

Mo Sodwatana, Stanford University, Stanford, CA, United States, Saif Kazi, Kaarthik Sundar, Adam Brandt, Anatoly Zlotnik

We propose an optimization formulation for locational pricing of energy transported through a pipeline network that carries mixtures of natural gas and hydrogen from distributed sources to consumers. The objective includes the economic value provided by the pipeline to consumers of energy and suppliers of natural gas and green hydrogen, as well as incentives to lower carbon emissions by consuming the latter instead of the former. The optimization is subject to the physics of gas flow and mixing in the pipeline network as well as engineering limits. In addition to formulating this mathematical program, we synthesize the Lagrangian and derive analytical expressions for the dual variables. We propose that the dual solution can be used to derive locational marginal prices of natural gas, hydrogen, and energy, as well as the decarbonization premium paid by consumers that receive hydrogen. We derive several properties of solutions obtained using the proposed market mechanism, and demonstrate them using case studies for standard 8-node and 40-node pipeline test networks. Finally, we show that optimization-based analysis of the type proposed here is critical for making sound decisions about economic policy and infrastructure expansion for blending green hydrogen into existing natural gas pipelines.

3 - Co-Optimization of Industrial, Fuel Supply, and Electricity Sector Models

Maxwell Brown, Colorado School of Mines, Golden, CO, CO, United States

I present on the methodology and implications of linking two high-resolution representations of the electricity and industrial sectors in a co-optimization framework. The results focus primarily on the differences of standalone versus coupled representations under decarbonization scenarios.

4 - Evaluating the impacts of technology and policy drivers on US energy system decarbonization

David Young, EPRI, Palo Alto, CA, United States, John Bistline, Geoffrey Blanford, Aranya Venkatesh

Policy drivers, such as the Inflation Reduction Act (IRA) and the EPA 111 power plant rules for existing and new sources, are expected to support decarbonization of the U.S. energy system and pathways to meet the U.S. Nationally Determined Contribution targets. How emerging technologies may evolve will also strongly impact decarbonization trajectories. In this study, we use EPRI's U.S. Regional Economy, Greenhouse Gas, and Energy Model (US-REGEN) framework to develop scenarios illustrating how the U.S. electric sector may respond to a range of policy and technology drivers. These include uncertainties in the technoeconomic performance and infrastructure constraints of emerging technologies such as carbon capture and storage and hydrogen, as well as sensitivities around IRA incentives and the 111 rules. US-REGEN includes a detailed dispatch and capacity expansion model of the electric sector, along with additional models that represent U.S. energy end-use and fuel production, conversion, and transportation. For each scenario, we examine and compare impacts on electric capacity, generation, and CO2 emissions, and highlight difference in regional outcomes.

5 - Competitiveness of underground thermal energy storage in electricity system

Alicia Wongel, Carnegie Science, Stanford, CA, United States, Austin Vernon, Ian McKay, Ken Caldeira

Thermal energy storage can help shift demand peaks in electricity systems. Different forms of energy storage may play an increasingly important role in reliably meeting electricity demand, helping to shift electricity from times of abundant generation to times of high residual demand. However, most storage technologies currently available come at a high cost. In this study, we assess under which conditions underground thermal storage with low energy cost could become cost-effective in electricity systems reliant on natural gas or on wind and solar generation. We find that in electricity systems reliant on natural gas, underground thermal storage could play a limited role in helping meet seasonal demand peaks, with some saving in natural gas capacity and fuel costs; in electricity systems reliant on wind and solar generation, underground thermal storage could play a substantial role in cost-effectively reducing wind and solar capacity required to satisfy loads thus reducing overall system cost.

Advances in Sustainable Operations From Social and Environmental Perspectives

Invited Session

ENRE: Environment and Sustainability

Chair: Osman Alp, University of Calgary, Calgary, AB, Canada

1 - Self-Assessments for Supplier Sustainability: An Empirical Analysis

Tarkan Tan, University of Zurich, Zurich, Switzerland, Vrushali Patil, Shaunak Dabadghao, Sonja Rispens, Evangelia Demerouti

Large companies are increasingly accountable for the social and environmental impact of their suppliers. To ensure compliance, many companies implement sustainability standards and conduct audits. However, issues such as audit fraud, bribery, and fatigue undermine the accuracy of these audits. As a result, firms are shifting from a policing to a collaborative approach with suppliers, focusing on supplier self-assessment (SA). For instance, Philips BV requires suppliers to provide structured SAs with documentary evidence, promoting a trust-based rather than punitive approach. This method reportedly improves visibility of sustainability issues, engages suppliers more effectively, and enhances sustainability over time. Other companies like Volvo, Aldi, Home Depot, and Sanofi also adopt similar approaches. Despite these benefits, the accuracy of SAs remains a concern. Suppliers might manipulate their responses to appear more favorable to buyers. Factors contributing to inaccuracies include lack of time, resources, or understanding of the assessment parameters. Inaccurate SAs hinder buyers from mitigating sustainability risks and making informed improvement actions. In this talk we focus on enhancing the effectiveness of the SA approach considering these inherent inaccuracies. We analyze SA scores from 120 of Philips' Chinese suppliers (2016-2021) and compare them with validated (VAL) scores obtained through onsite visits. Using multi-linear regression analysis and t-tests, we investigate which sustainability dimensions have more accurate SAs, whether accuracy improves with multiple SA cycles, and how supplier characteristics like size, country, and relationship strength affect accuracy. Our goal is to help buyer firms predict inaccuracies and better target their validation and improvement efforts.

2 - Socially Efficient Rooptop Solar Energy Policies

Osman Alp, University of Calgary, Calgary, AB, Canada

In this talk, we consider alternative approaches for rooftop solar energy adoption that maximizes the benefit to various stakeholders in the society.

3 - Managing Product-Reusability Under Supply Disruptions

Prashant Chintapalli, Ivey Business School, Western University, London, ON, Canada, Kumar Rajaram, Nishant Kumar Verma

We model and analyze product reusability, executed through refurbishment, amidst potential supply disruptions. Consumers can trade in used units, which can later be refurbished and sold. Using a three-period model, we determine the optimal degree of product reusability, trade-in and refurbishment policies, trade-in fee, and the prices of new and refurbished units chosen by the firm.

4 - Who Leads the Way? Buyer vs. Supplier Initiatives in Supply Chain Carbon Footprint Reduction

Elif Kuscu, University of Zurich, Zurich, Switzerland, Ozgen Karaer, Tarkan Tan

We study two supply chain models: (i) Buyer-Led Supplier Development and (ii) Supplier-Led Supplier Development, which are consisting of a buyer and a supplier. We analyze which player should initiate the carbon footprint reduction efforts in the supply chain under a scope 3 emission tax by using different levers. The supplier, as the producer, may invest to reduce the product carbon footprint. The buyer, as the downstream partner, may incentivize the supplier through supplier development initiatives. In the buyer-led model, the buyer offers a wholesale price premium rate contingent on improvement, and the supplier decides her carbon footprint reduction efforts accordingly. In the supplier-led model, the supplier offers sharing the carbon footprint reduction investment cost and the buyer decides the improvement level. We compare these two models and gain insights into their effectiveness under varying market conditions. Our results show that carbon footprint reduction is guaranteed if the supplier takes the lead, however, a wider range of improvement opportunities occur when the buyer initiates the reduction effort.

Industrial Decarbonization III: Computational Perspectives for Promoting Industrial Decarbonization

Invited Session

ENRE: Other Energy

Chair: Paritosh Ramanan, Oklahoma State University, Stillwater, OK, United States

Co-Chair: Paritosh Ramanan, Oklahoma State University, Stillwater, OK, United States

Co-Chair: Zheyu Jiang, Oklahoma State University, Stillwater, OK, 74078, United States

1 - Decarbonization of Steam Cracking Units with joint Power System Planning

Steam cracking is the most prevalent petrochemical process that uses high temperature heat to break down hydrocarbons, such as natural gas and naphtha, into more valuable unsaturated hydrocarbons such as ethylene and propylene, which are the building blocks of polymers and other specialty chemicals. Steam cracking units around the world produce over 150 million tons of ethylene and propylene every year. Due to its endothermic nature, significant heat duty is required for steam cracking and downstream processes. It is estimated that steam cracking itself accounts for 8% of the total primary energy in chemical industry. As chemical companies are setting ambitious sustainability goals and greenhouse gas emission reduction targets, active research and development is undergoing to replace highly fossil intensive cracking furnace with electrified furnace, which can be powered by (variable) renewable electricity (VRE). For example, in June 2022, Dow Chemical and Shell announced its startup of the first experimental electrified cracker unit in Amsterdam. These ongoing trends in decarbonizing steam cracking via electrification establish unique opportunities and challenges from an operational perspective. First, it is expected that conventional crackers will still the abundant in the foreseeable future, as it is capital intensive to simply replace existing heat-driven crackers with new electrified crackers. Second, due to the installation of electrified crackers, chemical plants will become microgrids that possess a diverse energy portfolio, ranging from conventional fossil-based heat to electricity as well as other energy carriers such as hydrogen. Thus, operational challenges emerge as electrified chemical plants need to be integrated with the power systems. To systematically address these complications, in this talk, we present a comprehensive modeling and optimization framework that coordinates the operation of both conventional heat-driven crackers and electrified crackers with power systems that are becoming more intermittent due to increasing VRE proportions. First, we develop a first principle model to quantify the power demand of conventional and electrified cracking, subject to specific feedstock constraints as well as purity and yield targets. The resulting differential algebraic equation (DAE) based model is then incorporated into an optimization framework to determine the minimum heat duty/power requirement, which is subsequently embedded in an optimization formulation that encompasses the unit commitment of connected power systems. To tackle the computational challenges associated with the resulting a large-scale MILP problem, we adopt Bender's decomposition and partition the original problem into a master problem (unit commitment) and subproblems (microgrids). The microgrid subproblems, which are themselves MILPs due to the hourly decision making required for multiple energy conversion and storage units involved, undergo relaxation of binary variables followed by primal recovery to introduce integrality cuts into the master problem. This decomposition approach enables efficient optimization by exploiting the structure of the problem and reducing computational complexity. Our case study of steam cracking electrification in Texas demonstrates the tractability of the proposed modeling and optimization framework and shows that significant greenhouse gas emission reduction can be achieved.

2 - Importance Sampling in Variational Autoencoders to generate Industrial Carbon Emissions Scenarios

Huynh Quang Nguyen Vo, Oklahoma State University, Stillwater, OK, United States, Paritosh Ramanan

Concerns about the negative environmental impact of fossil fuels have spurred significant interest in decarbonization efforts. Renewable energy remains a key focus in these efforts but faces numerous challenges due to uncertainties in supply and demand. Stochastic programming provides a powerful framework for decision-making under such uncertainties. A key technique to effectively solve these problems is scenario generation, which organizes stochastic process outcomes into finite discrete distributions, facilitating mathematical programming models. The solutions to stochastic programs are heavily influenced by the quality of the generated scenarios, whose fidelity being a significant concern in decentralized applications. A major issue is the likelihood of scenario occurrence. In this talk, we explore the potential of variational auto-encoders (VAEs) and their decentralized variants in importance sampling, a method for computing mathematical expectations with respect to a target distribution - specifically, the scenario distributions - to address this challenge effectively.

3 - Decarbonization of Chemical Process Industries via Electrification

Zheyu Jiang, Oklahoma State University, Stillwater, OK, United States, H M Mohaimanul Islam

In 2018 the US manufacturing sector used ~20% of the country's primary energy and emitted ~18% of its total greenhouse gases (GHGs). The top two US energy-use processing industries, namely the chemicals and petroleum refining industries, use nearly half of the manufacturing sector's primary energy and emit half of its GHGs. The majority of the process energy use in these sectors is for process heating. Currently, almost all this process heating is either met by the direct combustion of fossil fuels or through the use of steam that is generated directly or indirectly through the combustion of fossil fuels. Historically, for process heating applications, there has been a choice whether to use heat from the combustion of fossil fuels or to convert the combustion heat to electricity and then use the generated electricity. In this case, the extra cost and efficiency loss due to conversion to electricity does not really stand out compared to using combustion heat directly. However, as the US energy landscape continuous to shift toward decarbonized electricity, mostly solar and wind, the energy can be directly harvested as electricity, which makes it worth examining the potential impact of replacing combustion heat with electricity. Through simple calculations, we show that if all this heat was to be provided by resistive electrical heating, this would translate to roughly 36% of the U.S. electricity generation. Such a large power demand for just heating applications will put a huge strain on electric power infrastructure.

4 - Decentralized Operations Planning of Decarbonized Chemical Plants with Renewable-driven Transmission Systems

Richard Reed, Oklahoma State University, Stillwater, OK, United States, Paritosh Ramanan, Saba Ghasemi Naraghi, Zheyu Jiang

As the electrification of industrial process heating becomes common it is increasingly important to integrate clean energy from power systems into chemical plant processes. However, integrating private chemical plant operations with the public power grid raises privacy concerns. Decentralizing large-scale unit commitment in power systems and electrified chemical process heating in a mixed-integer problem can maintain this privacy, encouraging stakeholders to adopt renewable energy use, thereby aiding decarbonization efforts. In this talk we will discuss decentralized optimization techniques that implement iterative ADMM to reach a consensus. We demonstrate that by limiting shared information through decentralization, it is possible to satisfy demand needs of the chemical plant while maintaining the privacy of its' operations. This approach eliminates the need to move data while considering operational constraints of the power system and chemical plant, while procuring expected results and retaining the privacy of operations.

1 - Mixed-Integer Programming Models for Solving Semi-Cooperative Attack Graphs Problems

Phanuel Allaissem Beremadji, University of Arkansas, Fayetteville, AR, United States, Robert Curry

In this paper, we investigate the Semi-Cooperative Attack Graph (SCAG) problem, focusing on optimizing attack strategies in interdependent infrastructures. We propose two mixed-integer programming (MIP) models to minimize the time required to complete attacks, accounting for shared resources and budget constraints among multiple attackers.

The first MIP model (MIP-C) uses continuous time variables and binary variables to track the time each state is reached and by which attacker. The second MIP model (MIP-D) utilizes discrete time periods and binary variables to determine if an attacker reaches a state during a particular time period. Both models are enhanced with valid inequalities and strategic parameter settings to improve computational efficiency and strengthen the linear programming relaxation. We finally present a series of computational results to explore the efficacy of both modeling approaches.

The SCAG model can model attacks on systems across various domains, including wireless sensor network security and defense strategies for interdependent infrastructures. The models contribute to a more comprehensive understanding of attack dynamics and optimization in real-world scenarios by considering cooperative attack scenarios where multiple attackers leverage shared resources.

2 - Survival Signature Estimation Using Optimization and Monte-Carlo Simulation for K ≥ 3 Classes of Nodes on Two-Terminal Networks.

Md Sazid Rahman, University of Arkansas, Fayetteville, AR, United States, Kelly Sullivan

This research develops an efficient approach to estimating survival signatures for two-terminal networks with more than two classes of components. Recently, the survival signature has gained substantial attention in the literature on network reliability estimation due to its unique separability property, which enables passing the network topology information independent of the failure distribution of the components. Following recent results from the literature, estimating the survival signature by Monte Carlo simulation entails solving a multi-objective maximum capacity path problem on a two-terminal network in each replication. We adapt a multi-objective Dijkstra's algorithm from the literature to construct the set of non-dominated paths solving the multi-objective maximum capacity path problem for each replication of the Monte-Carlo simulation. We have carried out experiments on random two-terminal networks and grid networks with three, four, and five classes of components. In these experiments, our version of the multi-objective Dijkstra algorithm was compared against four benchmark algorithms and an improvement technique that prunes some paths to be explored in the multi-objective Dijkstra algorithm setting lower bounds on capacities. We compared the run-time of our approach with all these benchmark approaches and found that the multi-objective Dijkstra algorithm performs significantly better in most instances.

3 - Maximum Flow Stochastic Network Interdiction with Uncertain Restructuring

Farhatul Janan, Clemson University, Clemson, SC, United States, Thomas Sharkey, Emily Tucker

We study the max flow stochastic network interdiction problems with uncertain restructuring (MF-SNIP-UR). In order to capture the underlying uncertainty associated with MF-SNIP-UR, we focus on the instances where interdictions may not be successful and where restructuring after successful interdictions happen stochastically. We propose a two-stage stochastic model (2S-SM) for this problem where the attacker makes the interdiction plan in the first stage, the network stochastically restructures based on the realization of successful interdictions, and then solves a maximum flow problem in the resulting network for the scenario. In addition, we capture the practical considerations that planned interdictions and then the resulting successful interdictions for each scenario should follow climbing the ladder constraints. We formulate the 2S-SM problem as a bi-level mixed integer problem (MIP) and then we convert it to a single-level MIP using the properties about restructuring and standard duality concepts. We examine sample average approximation (SAA) approaches to solve the single-level formulation of 2S-SM problem. We propose a fast approximation of the full 2S-SM by examining partial network formulations, which help find a valid lower and upper bound on the full network. This approximation can solve problems that have at least four times the number of scenarios as the original SAA approach. We demonstrate the importance of our problem by examining applications in drug trafficking networks.

4 - Parcel Truckload Trucking: Solving UPS's Large-Scale Network Design Challenge

Belgacem Bouzaiene-Ayari, UPS, Parsippany, NJ, United States

UPS possesses the world's largest integrated parcel truckload (PT) network, spanning across multiple service types and supported by an extended set of center and hub locations and a sophisticated multimodal transportation system featuring an arrays of equipment types. Both strategic hub placement and demand routing are pivotal factors in establishing such a network that fulfills service commitment under various operational constraints, while minimizing the total operational cost. This cost is composed of two components: the transportation expenses and the package handling cost incurred at the consolidation hubs. The network configuration must consider several other constraints revolving around: (a) equipment and driver management, (b) capacity of the sorting operations conducted at the various network hubs, (c) restrictions on feasible transportation modes by service type, and (d) the number of inbound and outbound doors available at the network facilities.

In this study, we formulate the problem of creating an efficient network configuration as a network design problem. Our model is defined on a compact space to ensure scalability. Additionally, we propose a novel solution approach based on well-established decomposition techniques such as column generation, benders decomposition, and Lagrange relaxation. Under the assumption of consistent demand throughout the planning horizon, the model and its algorithmic approach have been proven to deliver high-quality solutions for large-scale problem scenarios encompassing up to five thousand sorting operations, four million arcs, and two million origin-destination demand pairs.

Redistricting

Invited Session

Computing Society

Chair: Soraya Ezazipour, Oklahoma state university, Stillwater, OK, United States

Co-Chair: Maral Shahmizad, Oklahoma State University, Stillwater, OK, United States

1 - Political districting to maximize whole counties

Maral Shahmizad, Oklahoma State University, Stillwater, OK, United States

When drawing contiguous, population-balanced political districts, how many counties can be kept whole, i.e., not split across multiple districts? To answer this question, we propose a combinatorial Benders decomposition algorithm. The main problem decides which counties to keep whole, and the subproblem coarsens the selected counties and attempts to find a feasible plan. Key to the approach's success is a new class of valid inequalities. We apply the approach to all congressional and legislative districting instances across the USA and find provably optimal solutions for most of them. Our code and results are available on GitHub.

2 - Political districting to optimize the Polsby-Popper compactness score

Soraya Ezazipour, Oklahoma state university, Stillwater, OK, United States

In the academic literature and in expert testimony, the Polsby-Popper score is the most popular way to measure the compactness of a political district. Given a district with area A and perimeter P, its Polsby-Popper score is given by $(4 \pi A)/P^2$. This score takes values between zero and one, with circular districts achieving a perfect score of one. In this paper, we propose the first mathematical optimization models to draw districts with optimum Polsby-Popper score. Specifically, we propose new mixed-integer second-order cone programs (MISOCPs), which can be solved with existing optimization software. We investigate their tractability by applying them to real-life districting instances in the USA. Experiments show that they are able to: (i) identify the most compact majority-minority districts at the tract level; (ii) identify the most compact districting plans at the county level; and (iii) refine existing tract-level plans to make them substantially more compact. Our techniques could be used by plaintiffs when seeking to overturn maps that dilute the voting strength of minority groups. Our python code and results are publicly available on GitHub.

3 - Local Walks and Network Partitioning for Discrete Redistricting Problems

Daryl DeFord, Washington State University, Pullman, WA, United States

Many redistricting problems, including drawing electoral boundaries in the USA, are naturally modeled as graph partitioning problems, which allows for analysis using discrete optimization and sampling methods. Applying this approach successfully in practice requires both operationalizing legislative text and exploring complex Pareto frontiers and in recent years spanning tree-based approaches have become popular for generating large samples of comparison plans. In this talk I will discuss recent applications and extensions of these techniques, including for court cases, support of line-drawing commissions, and evaluating nonpartisan justifications for proposed plans. Along the way I will present related open problems and proposals based on the cycle basis walk and classic network partitioning methods including spectral clustering and modularity.

Preparing Interdisciplinary Leaders: Re-Imagine Your Department As A Place For Educating Future Operations Research Leaders Who Can Tackle Complex And Nuanced Problems

Plenary/Keynote Session

Plenary

Chair: Julie Ivy, University of Michigan, Ann Arbor, MI, United States

1 - Preparing Interdisciplinary Leaders: Re-Imagine Your Department As A Place For Educating Future Operations Research Leaders Who Can Tackle Complex And Nuanced Problems

Harriet Nembhard, Harvey Mudd College, Claremont, CA, United States

In the face of today's multifaceted global challenges, the role of Operations Research (OR) is more critical than ever. This plenary will explore how academic departments can be transformed into incubators for future OR leaders who are adept at addressing complex societal issues through interdisciplinary approaches. Beginning with a personal narrative, the talk highlights the urgent need for integrating diverse perspectives in OR education and practice. Drawing from successful initiatives at Harvey Mudd College and real-world applications, we discuss strategies for embedding interdisciplinary thinking, enhancing curricula, and fostering collaboration with industry and community partners. Participants will gain actionable insights on aligning academic programs with strategic goals, promoting effective leadership, and preparing students to create impactful, innovative OR solutions that contribute to achieving the UN Sustainable Development Goals (SDGs). This session aims to inspire and equip OR educators and practitioners to reimagine their departments as dynamic environments for training the next generation of leaders capable of making smarter decisions for a better world.

Data Analytics and Optimization for Smart Industry

Invited Session

Scheduling and Project Management

Chair: Lixin Tang, Northeastern University, Shenyang, N/A

1 - A Branch-and-Price Algorithm for Two-Stage Cutting Stock Problem based on Triple Transfer and One Feedback

Ying Meng, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, 110819, Shenyang, China, People's Republic of, Lixin Tang, Roberto Baldacci, Md AI Amin, Jiyin Liu, Marco A. Boschetti

The classical cutting stock problem (CSP) involves efficiently producing copies of items with different weights and demands using a minimal number of bins while ensuring that no bin exceeds its weight capacity. Various versions of CSPs have emerged to address specific constraints and objectives in different applications. This presentation focuses on a new one-dimensional two-stage CSP with flexible item sizes, known as the one-dimensional two-stage cutting stock with flexible item sizes problem (TSCSP), which arises in the steel industry. In the problem, each order is associated with a width range and a total demand. For the TSCSP, we develop the pattern-based mathematical formulation, and propose some valid inequalities to improve its linear programming relaxation. Then, an exact algorithm within a branch-and-price (BP) framework is developed to solve the problem optimally. In the exact algorithm, a novel label-setting-based pricing algorithm is designed for solving the pricing subproblems. A primal heuristic that relies on a depth-first heuristic search in the BP tree is also designed to speed up the solution process. We validate the method's performance through extensive computational experiments on benchmark instances from literature and real-world scenarios, confirming its effectiveness in solving TSCSP instances with up to 150 orders.

2 - Combinatorial Benders Approach for Quay Crane Scheduling Problem based on Triple Transfer and One Feedback

Defeng Sun, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, China, People's Republic of, Lixin Tang, Roberto Baldacci

In this paper, we propose an exact decomposition approach to solve the Quay Crane Scheduling Problem in container terminals. The problem is decomposed into two easier problems, i.e. a routing master problem and a scheduling sub-problem. The master problem probes possible routing solutions for quay cranes while the sub-problem determines the completion times of each task and each quay crane. Several types of valid inequalities are added into the master problem to significantly reduce the search space and improve the lower bound. Precedence-based combinatorial cuts and multiple cuts are generated to further accelerate the algorithm convergence with less computational effort. Computational tests on the benchmark instances verify the effectiveness of the proposed approach.

3 - Generalized Disjunctive Programming Modeling and Reinforcement Learning-based Optimization Method for Oxygen Production Scheduling based on Triple Transfer and One Feedback

Shengnan Zhao, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, China, People's Republic of, Lixin Tang

As one of the important energy media in steel production, oxygen production has the characteristics of energy-intensive and high emission. Steel companies can take advantage of optimal schedule of oxygen production to reduce energy cost and emission. In this work, we addressed an optimal scheduling problem of oxygen production in steel company with consideration of variable load of the oxygen production units. The problem is formulated as a generalized disjunctive programming (GDP) model and reformulated with hull reformulation method. The problem is then solved by a novel Lagrangian relaxation algorithm, in which a Q-learning method is designed to scientifically set the initial step size coefficient. Numerical experiments show that the proposed strategy can effectively improve the convergence speed.

4 - Data Circulation Mechanism and Technology to link Steel and Equipment Manufacturing Industries base on Triple Transfer and One Feedback

Gongshu Wang, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, 110819, China, People's Republic of, Lixin Tang

The steel industry plays a vital role in supplying raw materials to the equipment manufacturing sector, while the equipment manufacturing industry reciprocates by producing essential machinery serving the steel sector. Together, they form a Manufacture-Circulation Industrial System (MCIS) characterized by circularity. The industrial Internet serves as a critical infrastructure for connecting these industries in the digital realm. However, challenges arise due to data ownership issues, hindering data sharing and circulation. To address this, we've integrated various technologies like identity parsing, blockchain, and privacy computing to establish a robust data circulation mechanism.

Through identity parsing, unique identifiers are assigned to physical entities and virtual objects, ensuring traceability. Blockchain technology underpins a secure and orderly data circulation system, enhancing trustworthiness. Furthermore, privacy-enhancing technologies safeguard data security. Our goal is to facilitate dynamic data flows across enterprises by leveraging key technologies for data circulation.

5 - Modeling and Solution to Production and Inventory Planning Problem based on Triple Transfer and One Feedback

Yang Yang, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, China, People's Republic of, Lixin Tang

The production process of steel enterprise includes multiple production stages, and there is work-in-process inventory between two consecutive stages. Thus, the decision of production and inventory volume are closely related. Moreover, the production process inevitably involves logistics operation and energy consumption, and the information technology enables the information sharing among the different production stages. This talk studies a production and inventory planning problem based on triple transfer (production, logistics, energy transfer) and one feedback (information feedback). To describe the problem, a mixed integer programming model is formulated. Then a CG-BS algorithm, combining Column Generation (CG) and Beam Search (BS), is developed to solve the problem. Finally, the effectiveness of the algorithm is verified through the computational experiments.

Co-Chair: Moses Chan, Northwestern University, Evanston, IL, United States

1 - Active Learning for Multi-Fidelity Computer Experiments with Adaptive Non-Stationary Kernel Function

Romain Boutelet, Michigan State University, East Lansing, MI, United States, Chih-Li Sung

Simulating complex physical processes across a domain of input parameters can be very computationally expensive. Multi-Fidelity Surrogate Modeling can resolve this issue by integrating cheaper simulations with the expensive ones in order to obtain better predictions at a reasonable cost. We are specifically interested in computer experiments that involve the use of Finite Element Methods with a real-valued tuning parameter that determines the fidelity of the numerical output. In these cases, integrating this fidelity parameter in the analysis enables us to make inference on fidelity levels that have not been observed yet. Such models have been developed and we propose a new Adaptive Non-stationary Kernel Function which more accurately reflects the behavior of computer simulation outputs. In addition, we aim to create a sequential design based on the Integrated Mean Square Prediction Error (IMSPE) to identify the best design points across input parameters and fidelity parameter, while taking into account the computational cost associated with the fidelity parameter. We illustrate this methodology through synthetic examples and applications to finite element analysis.

2 - Gaussian Processes with Sparse Grids

Haoyuan Chen, Texas A&M University, College Station, TX, United States, Rui Tuo

Gaussian processes (GPs) are widely used in non-parametric Bayesian modeling, and play an important role in various statistical and machine learning applications. In a variety tasks of uncertainty quantification, generating random sample paths of GPs is of interest. As GP sampling requires generating high-dimensional Gaussian random vectors, it is computationally challenging if a direct method, such as the Cholesky decomposition, is used. In this paper, we propose a scalable algorithm for sampling random realizations of the prior and posterior of GP models. The proposed algorithm leverages inducing points approximation with sparse grids, as well as additive Schwarz preconditioners, which reduce computational complexity, and ensure fast convergence. We demonstrate the efficacy and accuracy of the proposed method through a series of experiments and comparisons with other recent works.

3 - Diverse Expected Improvement (DEI): Diverse Bayesian Optimization for Expensive Computer Simulators

Simon Mak, Duke University, Durham, NC, United States

The optimization of expensive black-box simulators arises in a myriad of modern scientific and engineering applications. Bayesian optimization provides an appealing solution, by leveraging a fitted surrogate model to sequentially guide simulator evaluations. In practical problems, however, the goal is often not to obtain a single good solution, but a "basket" of good solutions from which users can choose for downstream decision-making. This arises in our motivating application for real-time control of internal combustion engines (ICEs), where a diverse set of control strategies are desired for robust and timely control. Despite its importance, there has been little work on this front for Bayesian optimization. We thus propose a new Diverse Expected Improvement (DEI) method, which extends the well-known Expected Improvement method to encourage diversity between "ϵ-optimal" solutions, i.e., solutions with objectives within a small ϵ from a global optimum. The DEI jointly targets two goals: the exploration of ϵ-optimal regions on the solution space, and the exploitation of promising solutions that may improve upon the current best solution. One advantage of the DEI is that it admits a closed-form acquisition function under a Gaussian process surrogate model, which facilitates efficient sequential queries via automatic differentiation. We demonstrate the improvement of DEI over state-of-the-art methods for diverse optimization in a suite of numerical experiments. We then explore the DEI in two practical applications, the first on rover trajectory optimization and the second for real-time control of ICEs.

4 - Simulation Experiment Design for Calibration via Active Learning

Ozge Surer, Miami University, Oxford, OH, United States

Simulation models often have parameters as input and return outputs to understand the behavior of complex systems. Calibration is the process of estimating the values of the parameters in a simulation model in light of observed data from the system that is being simulated. When simulation models are expensive, emulators are built with simulation data as a computationally efficient approximation of an expensive model. Instead of repeatedly running an expensive simulation model during the calibration process, an emulator then can be used to predict model outputs. Sequential design with an intelligent selection criterion can guide the process of collecting simulation data to build an emulator, making the calibration process more efficient and effective. This presentation focuses on two novel criteria for sequentially acquiring new simulation data in an active learning setting by considering uncertainties on the posterior density of parameters. Analysis of several simulation experiments and real-data simulation experiments from epidemiology demonstrates that proposed approaches result in improved posterior and field predictions.

Co-Chair: Hao Yan, Arizona State University, Tempe, AZ, United States

1 - Average vs Tail: Extreme Pattern Discovery of Metro Passenger Flows

Kai Wang, Xi'an Jiaotong University, Xi'an, China, People's Republic of

Modern metro systems generate sheer amounts of passenger travel records every day. While most works in transportation research are devoted to exploring the day-to-day variation of passenger mobility from these big traffic data, the variation is measured with respect to the mean or average of traffic flows. The interest of this work, by contrast, lies in the tail of traffic flow distribution, which accounts for the extreme level of traffic demands and the day-to-day variation of which is more relevant to risk control or capacity planning in metro operations. By characterizing the traffic flow tail behaviors by generalized quantile, where quantile and expectile are two special cases, and representing all traffic flows within a day as a higher order tensor, we propose a novel generalized quantile tensor decomposition to unveil extreme patterns that are associated with the day-to-day tail variation. Specifically, we consider an asymmetric loss function that assigns different weights to different elements of tensor, and then adopt it to decompose the daily traffic flow tensor into a series of rank-one basic tensors, each of which contains extreme patterns for multiple traffic modes (e.g., flow type, passenger type, time in a day) and is further induced to be sparse and smooth by regularization for better interpretation. An efficient learning algorithm is designed based on the least asymmetrically weighted squares and alternating direction method of multipliers. Our proposed methodology is finally applied to the Hong Kong metro dataset.

2 - Personalized Tucker Decomposition with Exponential Family

Hao Yan, Arizona State University, Tempe, AZ, United States

We propose a generalized personalized Tucker Decomposition to distinguish and decouple the shared and unique information in tensor format from different sources. The shared information is modeled by a global shared tensor and localized unique tensors. Several case studies including image monitoring and disease hotspot detection will be studied.

3 - Total Monitoring of Causation-Based Multivariate Processes

Xiyao Wang, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Kaizong Bai, Jian Li

We consider monitoring multiple quality characteristics with causal relationships among them, and shifts occurring in cause variables may propagate to effect ones. Usually a Bayesian network (BN) can describe causation, where through directed arcs a variable depends on its direct cause variables. In the literature, some monitoring methods have been proposed based on BNs, but these approaches focus on merely the means of each variable. By fully exploiting the BN structure, we propose for each quality characteristic to monitor shifts in its mean and variance, as well as in the functional dependency on its direct cause variables, and therefore achieve total monitoring of causation-based multivariate processes. Specifically, we propose two causation-based control charts. The first chart serves as a general tool for process monitoring, while the second one incorporates directional information, enabling the identification of shift locations through a diagnostic prescription. Simulations have validated the effectiveness of the proposed monitoring and diagnostic schemes.

4 - Stream of Variation Modeling and Monitoring for Heterogeneous Profiles in Multi-Stage Manufacturing Processes

peiyao liu, Tsinghua University, Beijing, China, People's Republic of, Chen Zhang

Advanced manufacturing systems typically involve multiple operating stages, where in-process data are observed in the form of profiles that contain rich information for process monitoring. Emerging methodologies have been developed for multi-stage profile monitoring. However, the cases where different stages' profiles are heterogeneous and variations propagate over stages have not been addressed so far. To this end, this article proposes a heterogeneous profiles-based stream of variation (HP-SoV) framework for multi-stage manufacturing process monitoring. It uses functional decomposition to extract features of heterogeneous profiles from different stages, where the decomposition coefficients are regarded as latent states that propagate along consecutive stages to capture the variation propagation. HP-SoV includes many existing models as its special cases, and enjoys an efficient inference algorithm via maximum likelihood estimation. Based on the one-step-ahead forecast errors of HP-SoV, a group monitoring scheme is further developed for online monitoring. Extensive numerical studies explore the modeling robustness and monitoring effectiveness of HP-SoV under different settings. A case study demonstrates the applicability of HP-SoV in multi-stage process monitoring for heterogeneous profiles.

5 - GAN-based High-throughput Single Track Characterization to Reduce Variability and Experimental Costs in Laser Powder Bed Fusion Additive Manufacturing

Jiahui Ye, Texas A&M University, College Station, TX, United States, John Coleman, Gerald Knapp, Amra Peles, Chase Joslin, Alex Plotkowski, Alaa Elwany

Most process optimization methods in laser powder bed fusion additive manufacturing rely on single-track experiments as an efficient screening step. However, their variability due to melting pool instabilities is often overlooked. We propose a Generative Adversarial Network (GAN) based high-throughput single-track analysis method for rapid investigation of heteroscedastic variance in measurements while minimizing labor-intensive efforts. Coupling this method with physics-based defect criteria, we develop optimal process maps with uncertainty bands and further show how this approach easily applies to different processing conditions with minimal computational and experimental burden. This research was sponsored by National Science Foundation, the U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, Advanced Materials and Manufacturing Technology Office.

1 - Time-Varying Graph Learning for Unevenly Spaced Time Series Data

Masaki Takahashi, Graduate School of Information Science and Technology, Osaka University, Suita, Japan, Satoru Iwasaki

We propose a method for estimating the structure of time-varying graphs underlying time series data observed at unevenly spaced intervals at each vertex on the graph. We formulate the problem as a convex optimization problem, extending existing time-varying graph learning methods to unevenly spaced time series data without increasing the number of required hyperparameters. Additionally, we prove that both the existing method and our proposed method contain one unnecessary (not need to be tuned) hyperparameter. Moreover, we prove that the globally optimal solution of the formulated convex optimization problem can be obtained using the primal-dual splitting algorithm, and we provide an efficient algorithm. The effectiveness of our proposed method is also confirmed through several numerical experiments.

2 - Evaluation and Selection of Solution Procedures to Data-Driven Stochastic Programming: a Statistical Approach via Auxiliary Problems

Xianghua Gan, Southwestern University of Finance and Economics, Chengdu, China, People's Republic of

We investigate a data-driven stochastic programming (DDSP) challenge where the distribution of a random parameter from a predefined set is unknown and only inferred from observed samples. Existing literature presents various solution methods for DDSP, such as empirical optimization (EO), sample average approximation (SAA), operational statistics (OS), and distributionally robust optimization (DRO). Choosing the appropriate solution method is complex, especially with limited data. Each method offers a unique solution estimator that maps samples to real-valued solutions, with the operational risk of the DDSP problem depending on both the solution estimator and the random parameter. To estimate the solution estimator from an observed sample, we introduce auxiliary problems corresponding to each oracle distribution in the predefined set. Each auxiliary problem, mirroring the original, uses a sample from its specific oracle distribution. With infinitely many samples from an oracle distribution, we can precisely determine the true solution estimator and its operational risk for each auxiliary problem. The operational risk for the original problem is estimated using a weighted average of risks from these auxiliary problems, with weights based on the likelihoods of the oracle distributions derived from the observed sample. Additionally, we develop hypothesis tests to evaluate the performance of different solution procedures. We apply our methodology to a data-driven newsvendor problem, highlighting the acquisition of solution estimators, assessment of operational risks, and comparative analysis through hypothesis tests.

3 - Modelling Unstructured Information of External Events as Demand Sensing Signals using Generative AI

Belinda Soh, Singapore Institute of Technology, Singapore, Singapore, Shanshan Yang, Humza Akhtar, David Weidong Lin, Louiz Cheng Yin Lee, Wenda Chen, Ning Liu

Numerous studies have revealed a plateau in demand forecast accuracy in industry application. Demand planners tune the forecast accuracy based on their domain knowledge and understanding of market conditions. The accuracy of a forecast is thus subjected to human bias and the boundaries of the planner' experience. As the market grows more dynamic, comprehensively tracking market conditions manually becomes complex. Research and commercial applications have shown that inclusion of structured indicators such as weather to forecast demand models can be achievable. However, for market signals, they are largely unstructured data varying from quantitative to qualitative, and sometimes discrete. It is challenging for forecast models to comprehend such data. This paper makes first attempts to leverage on Large-Language Models to automate the knowledge acquisition and subsequent refinement into structured time-series data for input in forecasting models. In particular, the research will focus on real world events (i.e. disasters, civil/political conflicts, economic macrotrend) as input. The main contributions of the study are: (1) design for usage of vector database with Generative AI to process mined information on real world events into machine readable format; (2) development of a metrics framework to tackle the lack of standardized quantification of severity of real world events in existing demand sensing research (3) prove of significance of real world events' impact on demand based on correlation study using Time Lagged Cross Correlation and Dynamic Time Warping on the quantified indicator and real sales data taken from the M5 Competition.

4 - Optimizing Demand Forecasting for a Greener and Resilient Industry in the Competitive Market

Han Dong, Marriott International, Bethsda, MD, United States, Lokesh Merupula, Zhenzhen Zhu, Zelin Jiang

Due to the flexibility of return policies, high uncertainty, and competitions in the local market, traditional industries face significant challenges due to unpredictable demand, leading to inefficiencies and increased operational costs. This study presents an innovative bi-stage model for forecasting demand, integrating machine learning models with a two-stage approach to improve the accuracy, optimize resource allocation, and enhance resilience in the sector.

The model adopts a two-stage model structure. The first stage uses time series model to predict the demand in long term, while the second model refines these predictions by analyzing patterns in the demand over time to accommodate changes in short term.

The validation results of the model demonstrate its effectiveness in improving accuracy with uncertainties and reducing computing costs. Implementing this forecasting tool enables agents to make data-driven decisions, optimize production, and enhance inventory management, leading to more sustainable and efficient operations.

This research promotes sustainable practices in the industry. By reducing the uncertainty associated with demand, agents can better align operations with environmental objectives, contributing to a greener and more resilient industry.

5 - Forecast Linear Augmented Projection (FLAP): A free lunch to reduce forecast error variance

George Athanasopoulos, Monash University, Caulfield East, Australia, Fin Yang, Rob Hyndman, Anastasios Panagiotelis

A novel forecast linear augmented projection (FLAP) method is introduced. FLAP provably reduces the forecast error variance of any unbiased multivariate forecast without introducing bias. The method first constructs new series as linear combinations of the original series. Forecasts are then generated for both the original and new series. Finally, the full vector of forecasts is projected onto a linear subspace where the constraints implied by the combination weights hold. These new series are called components. It is proven that the trace of the forecast error variance is non-increasing with the number of components, and mild conditions are established for which it is strictly decreasing. It is also shown that the proposed method achieves maximum forecast error variance reduction among linear projections. The theoretical results are validated through simulations and two empirical applications based on Australian tourism and FRED-MD data. Notably, using FLAP with Principal Component Analysis (PCA) to construct the new series leads to substantial forecast error variance reduction.

Exploring Equilibrium in Games

Contributed Session

Chair: Paul Messinger, University of Alberta School of Business, Edmonton, AB, Canada

1 - Computing Extended Proper Equilibria and Perfect d-Extended Proper Equilibria with Compact Formulations

Chuangyin Dang, City University of Hong Kong, Kowloon, Hong Kong, Yiyin Cao

The concept of extended proper equilibrium was formulated by Milgrom and Mollner (2021) as a strict refinement of proper equilibrium, which further alleviates the ambiguity of Nash equilibrium. Nonetheless, the formulation of extended proper equilibrium has an unnecessarily strong requirement on strategy perturbations and consequently, demands extremely high computational precision so that it is costly to compute such an equilibrium when the problem size is even moderate. To mitigate this difficulty, we propose the concept of perfect d-extended proper equilibrium, where d is a given number for controlling the degree of extended properness. For each given game, there exists d_0 such that every perfect d-extended proper equilibrium is an extended proper equilibrium provided that d <= d_0. Examples show that a perfect d-extended proper equilibrium remains an extended proper equilibrium even when d is very large. Differentiable path-following methods are developed to compute extended proper equilibria and perfect d-extended proper equilibria. Incorporating logarithmic-barrier terms into payoff functions with an extra variable, we constitute a perturbed logarithmic-barrier game in which all the players jointly solve against a given mixed strategy profile a strictly convex optimization problem. We establish the existence of smooth paths to an extended proper equilibrium and a perfect d-extended proper equilibrium. To reduce the computational burden, we exploit the sorting networks to derive compact formulations of extended proper equilibrium and perfect d-extended proper equilibrium, which consist of a polynomial number of variables and equations. Comprehensive numerical results are reported to show the effectiveness and efficiency of the methods.

2 - Further Extended Proper Equilibrium: Theory, Computation, and Applications

Yiyin Cao, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Chuangyin Dang

Extended proper equilibrium, a refinement of Myerson's (1978) proper equilibrium, was initially formulated by Milgrom and Mollner (2021). In our research, we aim to refine the concept of extended proper equilibrium by introducing the notion of further extended proper equilibrium. This is achieved through the construction of a perturbed strategy space with the property that each of its linear inequality constraints with upper bounds consists of at least one strategy of every player. We show that every further extended proper equilibrium is an extended proper equilibrium. To address the challenges associated with numerical precision in further extended proper equilibrium, we propose the concept of perfect d-further extended proper equilibrium, where the parameter d (0 < d < 1) controls the degree of further extended properness. We rigorously prove that, for sufficiently small values of d, every perfect d-further extended proper equilibrium is indeed a further extended proper equilibrium. Moreover, we exploit logarithmic-barrier games to establish the existence of a smooth path to a further extended proper equilibrium and a smooth path to a perfect d-further extended proper equilibrium, which enable the development of differentiable path-following methods for computing such equilibria. Numerical results further confirm the effectiveness and efficiency of the methods.

3 - Analysis and Discussion of The WGA Strike of 2023

Lara Inci Kullu, Trinity Preparatory School, Orlando, FL, United States

In this paper, we study the Writers Guild of America strike of 2023. Writers are critical suppliers of the entertainment industry, which is a major service industry in the U.S. The strike affected not just the movie and television studios, but also the whole economies of California, Georgia, and New Mexico, placing the economic cost at more than 6 billion dollars. We look at the problem with analytical tools from labor economics and discuss equitable solutions for the industry as a whole and future research directions.

4 - Search and Predict: A Geometric-Inspired Algorithm for Finding Nash Equilibria

Taemin Kim, Rensselaer Polytechnic Institute, Troy, NY, United States, James Bailey

A standard approach for finding Nash equilibria in multiagent games is to apply online optimization algorithms such as gradient descent or multiplicative weights where the time-average of agent strategies are known to converge to the set of Nash equilibria. In this stream of research, we prove geometric properties for gradient descent in zero-sum and coordination games. We then exploit these geometric properties to directly compute a Nash equilibrium after accessing the output of a constant number of iterations of gradient descent. The proposed methods have the potential to drastically improve learning rates while simultaneously decreasing the number of queries/training points needed to find equilibria.

5 - Equilibrium Refinement for Asymmetrical Stackelberg Leadership Duopolies

Paul Messinger, University of Alberta, Edmonton, AB, Canada, Arjang Nikbakht, Bora Kolfal

Often in Stackelberg duopoly both firms prefer the same role (e.g., leadership). The current paper proposes an equilibrium refinement for role selection in such cases. The refinement shows how applying a performance criterion assures a form of perceptual congruence between the equilibrium outcomes and the assumed player roles: a very dominant (weak) firm cannot consistently be assumed to be the follower (leader). This paper gives a general tool for identifying and ruling out implausible leadership structures for the purpose of model design. Also, ruling out implausible equilibria makes the equilibrium predictions more managerially relevant. Lastly, applying this approach leads to game predictions that can be tested empirically.

Our approach assumes the difference in two focal parameters, like production costs, is the only source of asymmetry in the duopoly. Second, we identify all cases where at least one role selection is feasible based on both firms being profitable at the equilibrium. Third, we partition the feasible cases in the focal parameter space based on whether they satisfy particular performance criteria. This partition identifies qualitatively different regions that are characterized by various properties that we discuss. Finally, we categorize the implications for role selection for each region. We show six potential regions emerge for a general model; then we extend the model to include additional conditions that go beyond profitability of firms, which gives rise to three new regions.

Optimization and Game Theory in Power Systems and Sports

Contributed Session

Chair: Sreerag Choorikkat, National Tsing-Hua University, Hsinchu, N/A, Taiwan

1 - Dual Conic Proxies for AC Optimal Power Flow

Guancheng Qiu, Georgia Institute of Technology, Atlanta, GA, United States, Mathieu Tanneau, Pascal Van Hentenryck

In recent years, there has been significant interest in the development of machine learning-based optimization proxies for AC Optimal Power Flow (AC-OPF). Although significant progress has been achieved in predicting high-quality primal solutions, no existing learning-based approach can provide valid dual bounds for AC-OPF. This paper addresses this gap by training optimization proxies for a convex relaxation of AC-OPF. Namely, the paper considers a second-order cone (SOC) relaxation of AC-OPF, and proposes a novel architecture that embeds a fast, differentiable (dual) feasibility recovery, thus providing valid dual bounds. The paper combines this new architecture with a self-supervised learning scheme, which alleviates the need for costly training data generation. Extensive numerical experiments on medium- and large-scale power grids demonstrate the efficiency and scalability of the proposed methodology.

2 - The Madness of Multiple Entries in *March Madness*

Jeff Sylvestre-Decary, University of Connecticut, Storrs, CT, United States, David Bergman, Carlos Cardonha, Andrea Lodi, Jason Imbrogno

This paper explores multi-entry strategies for betting pools related to single-elimination tournaments. In such betting pools, participants select winners of games, and their respective score is a weighted sum of the number of correct selections. Most betting pools have a top-heavy payoff structure, so the paper focuses on strategies that maximize the expected score of the best-performing entry. There is no known closed-formula expression for the estimation of this metric, so the paper investigates the challenges associated with the estimation and the optimization of multi-entry solutions. We present an exact dynamic programming approach for calculating the maximum expected score of any given fixed solution, which is exponential in the number of entries. We explore the structural properties of the problem to develop several solution techniques. In particular, by extracting insights from the solutions produced by one of our algorithms, we design a simple yet effective problem-specific heuristic that was the best-performing technique in our experiments, which were based on real-world data extracted from recent *March Madness* tournaments. In particular, our results show that the best 100-entry solution identified by our heuristic had a 2.2% likelihood of winning a $1 million prize in a real-world betting pool.

3 - Strategic Interactions in the EV Li-Ion Battery Industry: a Game Theoretical Analysis of the Equilibrium Between Li-Ion Manufacturers, Recycling Companies, and Lithium Suppliers in An Epec Context

SREERAG CHOORIKKAT, National Tsing-Hua University, Hsinchu, Taiwan, YU- CHING LEE, HSIN- WEI HSU

This study delves into the strategic dynamics of the lithium-ion (Li-ion) battery supply chain using a game-theoretical approach and an Equilibrium Problem with Equilibrium Constraints (EPEC). It addresses the interactions among key players: Li-ion battery manufacturers, recycling companies, and lithium suppliers. Manufacturers and recyclers act as leaders in a competitive market, with lithium suppliers serving as followers, aiming to minimize costs under quantity, taxation, and budget constraints. A significant focus of this research is the integration of environmental taxes and subsidies. These economic instruments are explored for their potential to drive sustainable practices by influencing the production and recycling behaviors within the industry. The mathematical modeling of the study confirms the existence of equilibrium solutions that strategically utilize environmental taxes to optimize the sustainability of industry practices. Crossover points, or critical tax levels that lead to shifts in manufacturing and recycling behaviors are a crucial aspect of this study. These points are analytically identified to show how changes in tax incentives can lead to more environmentally friendly industry practices. The study's findings indicate that strategic use of crossover points in tax policies can significantly influence the quantities of Li-ion batteries manufactured and recycled, pointing to the potential of fiscal policies to foster a more sustainable battery supply chain. This research contributes valuable insights into policymaking by comprehensively understanding how economic incentives can be aligned with environmental goals.

4 - Enhanced critical node detection with beam search: A heuristic-agnostic approach

Faraz Khoshbakhtian, University of Toronto, Toronto, ON, Canada, Eldan Cohen, Dionne Aleman

This study presents a novel integration of beam search for the critical node detection problem (CNDP), a well-known NP-Hard combinatorial optimization problem with applications ranging from healthcare to social network influence. Beam search is a widely employed heuristic search algorithm for generating high-quality sequences of tokens in combinatorial search spaces. We leverage the versatility of beam search and tailor it for CNDP, setting our approach apart from existing heuristics by its heuristic-agnostic nature. This versatility enables compatibility and seamless application with various CNDP scoring heuristics. We introduce the doubly scored beam search for CNDP that ensures solutions are optimized both with respect to model outputs and the ground-truth connectivity objective. Our beam search-enhanced CNDP pipeline offers priority interpretation and an ordering of critical nodes, therefore, producing solutions that are effective at every budget level, not just at a threshold. Our doubly scored beam search algorithm has a time complexity of $O(b*w*n \log n)$ in sparse networks of size n, beam width w and budget b, which enables efficient exploration of the solution space, maintaining a balance between exploration and exploitation. We provide the first systematic evaluation of beam search approaches for CNDP in the literature, providing results for singly and doubly scored beam search, standard, diverse, and stochastic beam search, and classical and learning-based node criticality scoring mechanisms. Our empirical evaluations across diverse node-scoring heuristics, beam search variations, and network topologies demonstrate that our doubly scored beam search improves CNDP heuristics, often by double digit margins.

5 - A Mathematical Model for Break Minimization in Round Robin Tournaments

Nasser Salmasi, SimpleRose, Wilmington, NC, United States, Ali Hassanzadeh

In this study, we address the break minimization problem in round-robin sports scheduling tournaments. We focus on a mixed-integer linear programming (MILP) model designed to minimize consecutive home or away games, which are termed 'breaks'. Our framework incorporates advanced constraints and valid inequalities that significantly enhance computational efficiency. This allows for the rapid generation of schedules with minimal breaks for tournaments involving up to 30 teams. We present a detailed analysis of the model's complexity, demonstrating that our approach can solve instances previously deemed challenging by existing mathematical frameworks in mere minutes.

Optimization Approaches for Machine Learning

Contributed Session

Chair: Robert Parker, Los Alamos National Laboratory, Los Alamos, NM, United States

1 - Improving the efficiency of Logic-Based Benders Decomposition for large-scale optimization

Paulo Nascimento, Faculty of Sciences and Technology of the University of Coimbra, Coimbra, Portugal, Cristóvão Silva, Samuel Moniz, Christos Maravelias

Large-scale optimization, especially in NP-hard problems, presents significant challenges. To find near-optimal solutions for such problems within a reasonable time frame, (meta-)heuristics are commonly employed. However, when a proven optimal solution is needed, decomposition methods may be the only practical option. Logic-based Benders decomposition (LBBD) expands on traditional Benders decomposition by accommodating any type of optimization or constraint satisfaction problem as sub-problems, making it suitable for a wide range of complex optimization challenges. The problem is divided into a master problem and one or more sub-problems, which exchange information to converge to the optimal solution. Like most decomposition methods and optimization tools, however, the effectiveness of LBBD is heavily dependent on its construction. This study investigates methods to enhance LBBD's efficiency in the context of nesting and scheduling problems in Additive Manufacturing, and explores how these improvements can be generalized to other problems. Various techniques were examined to boost the efficiency of the models used in both the master and sub-problems. Moreover, extracting maximum information from the sub-problems can be computationally expensive, but this is usually offset by generating more effective cuts in the master problem. Additionally, when symmetrical optimal solutions in the master problem cannot be avoided, prioritizing those that are consistent with the solutions from the sub-problems can significantly accelerate the process. The findings suggest that strategic design of an LBBD can influence its computational performance by orders of magnitude, allowing to obtain optimal solutions in a short period of time, ultimately contributing to faster and better decision-making.

2 - GPU accelerated Linear Programming Solver for large problems

Nicolas BLIN, NVIDIA, Paris, France, Katrine Scheel, Piotr Sielski, Akif Coerduek, Rajesh Gandham, Thejaswi Nanditale, Alex Fender, Joe Eaton

Linear programming (LP) is an essential tool for optimization and has applications in resource allocation, production planning, logistics and, as a backbone for Mixed Integer Programming (MIP) solvers. Most of the research and development has been focused on CPUs and direct solvers which require matrix factorization, thus limiting the size of the problems we can solve in a reasonable time. Recent research has been more focused on First Order Methods (FOM) which are more well-suited for parallelization on the latest computing architectures. We introduce a GPU implementation of PDLP, a new FOM algorithm proposed in [1]. It allows us to scale to Linear Programs containing millions of variables and constraints. We observe up to 100x speed up compared to the CPU-based solver.

In this talk, we will discuss how using state-of-the-art CUDA libraries and programming tools allowed us to map PDLP fully and in a highly optimized manner onto the GPU. Furthermore, we will showcase how fine-tuning the hyper-parameters using genetic algorithms allowed us to further gain significant performance improvement. We will conclude by presenting scalability and performance results.

[1] Practical Large-Scale Linear Programming using Primal-Dual Hybrid Gradient

3 - Convergence Reliability of Surrogate and Implicit Formulations for Nonlinear Optimization

Robert Parker, Los Alamos National Laboratory, Los Alamos, NM, United States, Sergio Bugosen

Nonlinear optimization is a powerful tool for engineering and operations research practitioners. While second-order interior point methods such as IPOPT and KNITRO are popular, their successful convergence can be sensitive to model parameters, initial guess, and scaling factors. When this sensitivity is caused by a subsystem of equality constraints that is square and nonsingular (i.e. can be simulated in isolation), several methods are available to improve convergence reliability by replacing these constraints with “easier” functions or constraints. Here, we compare three alternatives that have been proposed to replace such constraints: Sparse polynomial surrogates computed by ALAMO [1], smooth neural network surrogates [2], and implicit functions [3]. In a recent chemical process optimization case study [4], an ALAMO surrogate leads to the most reliable convergence, followed by an implicit function formulation, followed by a smooth neural network surrogate, all of which outperform the original, full-space model.

4 - Large Language Models to Improve Defense Acquisition

Maurice Hudson, University of Alabama at Huntsville, Huntsville, AL, United States, Hieu Pham, Yi Tan

Many organizations are faced with the growing challenge of generating, analyzing, and tracking enormous amounts of text-based data to meet organizational needs. Simultaneously, these organizations are facing high rates of retirement which can lead to institutional knowledge loss and an inability to quickly recruit and sustainably retain personnel with in-demand expertise and knowledge. These challenges are particularly salient in the defense industry due to the complex and bureaucratic nature of Department of Defense (DoD) acquisition and the long lifecycle of those systems. This creates an opportunity to utilize LLM to improve the efficiency of businesses process. This study investigates the development of LLM Application to develop responses to DoD Request for Proposals (RFPs) with the goal of automating portions of the proposal development process and reducing cycle time.

5 - Eligibility threshold selection in social assistance programs: Targeting the poor from self-targeted population

Yuanzheng Ma, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Guodong Lyu, Chung Piaw Teo, Huan Zheng

Social assistance programs (SAPs) aim to utilize limited budget to serve as many households in need as possible. Targeting is the process of identifying and reaching out to households truly in need. However, targeting is challenging due to 1) limited prediction power on households’ welfare levels, and 2) the applicants of SAPs are biased samples of the whole population due to self-targeting effect. These factors can result in high exclusion errors and leaving budget underutilized in SAPs. To improve targeting performance, we focus on the eligibility threshold decision, which determines applicants’ eligibility based on their predicted welfare levels. We first characterize the self-targeted applicant population in distribution shift and population scale, constructing corresponding estimators with performance guarantees; Then we provide a new policy embedding the estimators into eligibility threshold selections. The numerical results show that the proposed policy significantly outperforms the benchmark policy from practice and covers more people truly in need, especially when welfare prediction power is limited. Beyond SAPs, self-selection and threshold-based control decisions are widespread in many other areas, where we believe the proposed method can also provide potential benefits.

Innovative AI and Strategic Decisions: From NFTs to Enterprise Security

Contributed Session

Chair: Rohan Korde, Arizona State University, Tempe, AZ, United States

1 - Propensity for Job Replacement by Artificial Intelligence: An Empirical Analysis

Shenghan Xu, University of Idaho, Moscow, ID, United States, Eric Stuen

The impending integration of Artificial General Intelligence (AGI) presents a monumental shift in the global economy, prompting a critical examination of its impact on industries and career trajectories. This research aims to address the pressing business problem of anticipating and navigating the disruptive effects of AGI on employment landscapes. Drawing on a dataset of 4,762 occupations and employing a mathematical model to quantify job replacement probabilities, the study identifies key findings regarding various industries' susceptibility and educational levels' susceptibility to AGI disruption. It reveals an inverse relationship between education level and replacement probability, with doctoral or professional degrees offering greater resilience. Additionally, the paper explores emerging careers in sectors less susceptible to automation, such as the "Pleasure Economy." This study contributes to existing knowledge by providing insights and guidance to individuals, industries, and policymakers, enabling informed decision-making and adaptation strategies in the face of AGI-driven transformations. It emphasizes the importance of higher education in mitigating the impacts of technological displacement and highlights potential avenues for future job opportunities. Methodologically, the research employs rigorous analysis of contemporary economic theories coupled with examining private investment trends and emerging career trajectories. The dataset allows for a comprehensive assessment of job replacement probabilities across industries and educational levels. The main results underscore the significant variations in replacement probabilities across industries and educational levels, with implications for future workforce planning and educational frameworks. The findings emphasize the need for proactive strategies to foster an equitable and prosperous future amidst the evolving AI-driven landscape.

2 - Zero-Trust in LLM-integrated applications in enterprise networks

Deepti Singh, California State University - Long Beach, Long Beach, CA, United States

The integration of large language models (LLMs) into enterprise applications introduces new cybersecurity risks and challenges to traditional security models. We apply Zero Trust principles to develop a comprehensive access-controlled security framework that addresses the unique security challenges posed by LLM-integrated applications within corporate environments.Unlike a traditional enterprise application, an LLM-integrated application can work in dual-modality - user and process. As a user it can interact with the system, input data, and request actions, much like a human user would. An LLM-integrated application can monitor network logs, access corporate resources, and generate reports. As a process, it can handle requests, generate responses, and manage data in a traditional secured network infrastructure. It can respond to queries, give recommendations, or automate tasks. This dual functionality disrupts the traditional distinction between users and processes. Although it presents new opportunities for enhanced functionality and user interaction, it introduces new challenges for system design and security. Our framework involves validating, monitoring, and enforcing strict access control policies for LLM-integrated applications, with a focus on preventing prompt injection, data poisoning, and unauthorized access. The proposed ZT-AI-Access framework enhances cybersecurity by ensuring robust data protection and compliance with corporate policies, mitigating the risks associated with the unmanaged adoption of AI technologies which are not necessarily confined the an enterprise-owned network boundary.

3 - Multiple orders per job (MOJ) scheduling problems for orders with due dates and release times in a two-stage permutation flowshop

Rohan Korde, Arizona State University, Tempe, AZ, United States, John Fowler, Lars Moench

Amazon, Alphabet, Microsoft, OpenAI, and other firms are driving the innovation in large language models (LLMs), generative pre-trained transformer (GPT) applications, artificial intelligence (AI) applications, and cloud computing. This has created a significant demand for tensor processing unit (TPU), application-specific integrated circuit (ASIC), field-programmable gate array (FPGA), graphics processing unit (GPU), and other semiconductor chips. The demand for semiconductor chips is expected to keep rising in the months and years ahead, as increasing number of companies adopt AI models to make smarter decisions. In a 300-mm wafer fabrication facility semiconductor chips are manufactured in reentrant process flows using hundreds of tools. Front opening unified pods (known as FOUPs or jobs) transport 300-mm silicon wafers between the tools in the fab using an automated overhead hoist transportation system (OHT). The number of FOUPs are typically far fewer than the number of customer orders received. In some cases, customer orders are prioritized and can be combined into a single FOUP depending on certain factors. The FOUPs are then scheduled to be processed on tools to minimize a given performance measure. These scheduling problems are known as "multiple orders per job" (MOJ) problems. We study MOJ scheduling problems to minimize maximum lateness, number of tardy orders, weighted number of tardy orders, total tardiness, and total weighted tardiness for orders with equal and unequal release times in a two-stage permutation flowshop. We design full-factorial experiments to check optimality (small-sized instances) and solution quality (large-sized instances).

4 - Why Firms Buy: Dynamic Games of Acquisition Among Tech Giants

Boyoon Chang, University of Oregon, Eugene, OR, United States

Information and technology markets often feature high market concentration and frequent acquisitions. Understanding the motives underlying these acquisition strategies is therefore a first-order question for policy makers and practitioners. Using a dynamic model, I analyze acquisition records of the “big five” (or “tech giants”) – Google, Amazon, Microsoft, Meta, and Apple. I characterize the firms’ acquisition decisions observed in the data as a Markov perfect equilibrium that is driven by their scale economies and defensive motive. I find that the motive to keep up with their rivals can explain a major share of their acquisition behaviors, sometimes overshadowing their internal motives of scale economies. I show that a company might opt to acquire not necessarily because it can benefit from technological synergies generated from accumulating similar targets, but to align with the trajectories of their rivals to mitigate the risk of falling behind.

5 - Prediction of Violence Victimization Among Children and Adolescents Using Machine Learning

Jennifer Mendoza-Alonzo, Division of Injury Prevention, National Center for Injury Prevention and Control, Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States, Ketra Rice, Elizabeth Parker, Keming Yuan

Violence victimization among young people is a significant public health problem in the United States. In 2021, there were over 3,000 homicides and over 160,000 emergency department visits for nonfatal assault injuries among young people ages 10-19 years. Violence victimization has significant long-term effects on the physical, social, and emotional health of youth, families, and communities. This study aims to predict violence victimization using social-ecological factors across the individual (i.e., race and ethnicity, attention functioning, gender identity), relationship (i.e., household financial stress, family relationship, peer relationships), and community (i.e., neighborhood safety) levels of the social ecology. Using 2019-2022 data from the Adolescent Brain Cognitive Development® (ABCD) study, we implemented classification models to understand this relationship using different machine learning algorithms such as logistic regression, support vector machines and eXtreme Gradient Boosting. Preliminary results show statistically significant associations between violence victimization and attention functioning ($p < 0.001$), family relationship ($p<0.001$), and neighborhood safety ($p=0.001$). Low attention functioning was found to have a 1.2 greater odds of victimization compared to adolescents with high attention functioning and living in a safe neighborhood was found to have a 0.60 lower odds of victimization compared to adolescents living in unsafe neighborhoods. The outcomes of the study revealed significant insights into the risk of violence victimization among adolescents and highlighted the importance of leveraging advanced computational techniques in addressing complex issues. Continuing research in this domain holds promise for further refining predictive models and enhancing their applicability in real-world settings to safeguard the well-being of adolescent populations.

Operating Online Platforms in the New Age

Invited Session

Auctions and Market Design

Chair: Jiaqi Lu, the Chinese University of Hong Kong (Shenzhen), Shenzhen, N/A

1 - Content Rotation in the Presence of Satiation Effects

Xiao Lei, University of Hong Kong, Hong Kong, Hong Kong, Beichen Wan, Shixin Wang

Service providers often employ rotational schedules for offering products such as fitness courses, game content in online video games, and new episodes on content-sharing platforms. These rotations not only reduce the operating costs associated with constant offerings, but also moderate consumer satiation caused by frequent consumption of the same product. Although simple designs are prevalent in practice, there is a lack of guidance on designing effective rotational schedules. In this paper, we explore the design of rotational schedules for service providers to maximize long-run average profits. We develop an analytical model based on utility theory, which connects consumer consumption with satiation and product correlation. Our investigation covers various scenarios, including single product offerings, regular and rotational product pairs, and multiple product assortments. For a single product, we characterize the optimal frequency. For a regular and rotational product pair, we observe an interesting ripple effect in consumer dynamics. In this case, we examine the optimal frequency and selection of the rotational product, which depend on reciprocal influences between the two products. In scenarios involving multiple products, we demonstrate that as the number of products increases, the assortment depth converges to a constant, and the cycle length should grow linearly. Additionally, we find that product permutations have a marginal impact on total consumption. To address general situations, we introduce a numerical method based on mixed-integer programming and conduct numerical studies using both synthetic and real data. Our findings and insights offer a first step towards understanding the design of content rotation.

2 - Dynamic Persuasion Strategies for Mitigating the Spread of Fake Content

Wenjuan Li, HKUST Business School, Clear Water Bay, Hong Kong, Dongwook Shin

Digital platforms allow users to create and share content on an unprecedented scale, but fake news and misinformation can quickly spread, posing a threat to society. Our research investigates how platforms can detect fake content and influence user actions using personalized recommendation messages. Our model involves random inspections of content by the platform, allowing it to determine the authenticity of the content once it has been inspected. We characterize optimal inspection and recommendation policies, finding that ad-based platforms may recommend fake content, while subscription-based platforms reveal true fakeness. We compare these results with public recommendation policies. Furthermore, we investigate the impact of the inspection and recommendation policies on content creators.

3 - Contract Design in Fulfillment by Platform

Xingyu Lin, Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Jingqi Wang, Jiaqi Lu, Yilun Chen

We study a third-party seller selling a product through an online platform, where the seller can fulfill his demands either by inventory stored in the platform's fulfillment center or by in-house inventory. We characterize the optimal FBP (Fulfillment by Platform) contract with sales profits sharing and inventory storage fee offered by the platform. We show that FBP coordinates the supply chain with a single seller. With the optimal contract, the platform extracts all surplus above the seller's reservation profit and will give a subsidy to the seller. For further discussion, we find that FBP also coordinates the supply chain with multiple sellers selling substitute products. We also analyze how FBP influence the platform's profit compared with FBS (Fulfillment by Seller), and demonstrate that this impact is related to seller's type (production costs, in-home inventory costs, etc). This leads us to a further model extension of the contract design when sellers have private information.

4 - Optimal Signaling of Supply Competition in Decentralized Platforms

Yanwei Sun, Imperial College Business School, London, United Kingdom, Niloofar Zamani Foroushani, Zhe Liu, Jiahua Wu

We consider a specific type of decentralized platforms prevalent in the service sector, characterized by a system where customers can freely post jobs or tasks on one side, while service providers must pay a fee to unlock the ability to communicate with customers. The purchase of job leads is not exclusive, permitting several service providers to access the same job lead. We employ a Bayesian persuasion framework to explore how the platform can leverage its informational edge concerning the supplier base to strategically influence service providers' decisions, with the goal of maximizing its revenue. We characterize the structure of the optimal signaling mechanism, wherein the platform recommends a deterministic number of service providers to participate when the pool size is smaller than a threshold; otherwise, the recommendation randomizes between two consecutive numbers. Then, we endogenize the platform's pricing decision and show that coupled with an optimal fixed price, the optimal signaling mechanism generates a higher expected revenue than the optimal state-dependent pricing mechanism. Besides, more notably, within the policy space where information design and state-dependent pricing are considered jointly, information design with one fixed price remains optimal.

Summit - 330

Opioid Crisis and Health Systems Management

Contributed Session

Chair: Yijie Chen, Centers for Disease Control and Prevention, Atlanta, GA, United States

1 - Investigating Factors Associated with Willingness to Receive Treatment Among Adults Reporting Fentanyl use: a Machine-Learning Approach for Feature Extraction and Interpretation

Yijie Chen, Centers for Disease Control and Prevention, Atlanta, GA, United States, Nisha Nataraj, Xinyi Jiang, Matthew Gladden, Gery Guy, Deborah Dowell

The opioid overdose crisis has rapidly evolved with the availability of illegally made fentanyl (IMF), reshaping patterns of substance use and treatment engagement. In 2022, approximately 90% of the estimated 81,806 opioid-overdose deaths involved synthetic opioids excluding methadone, primarily IMF. Recent reports indicate that only about 1-in-3 individuals with an opioid use disorder received any past-year substance use treatment. This study investigates factors associated with willingness to receive treatment among individuals who use IMF. The National Addictions Vigilance Intervention and Prevention Program Addiction Severity Index-Multimedia Version tool collects a convenience sample from adults aged ≥18 years assessed for substance use treatment. Leveraging a natural gradient boosting (NGBoost)-based algorithm, we analyzed treatment assessment data (2018-2023) from adults who reported past 30-day IMF use, with variables including demographic characteristics, routes of administration, and concurrent substance use. We also incorporated spatial-temporal dynamics analysis to account for regional differences in fentanyl availability and use patterns across the United States. Self-reported days experiencing drug-related problems in the past 30 days, severity of family problems (index reflecting frequency and conflicts), and severity of psychiatric problems (index reflecting frequency and distress), were the top three variables associated with willingness to receive treatment. A higher willingness was associated with more frequent drug use, higher frequency and intensity of family problems, and experience of psychiatric symptoms, with complex interaction effects. Efforts to connect people to evidence-based treatment, before exacerbation of family conflicts or psychiatric issues, is important, especially given that IMF use is associated with increased fatal overdose risk.

2 - The Complexity-Interpretability Tradeoff Between Risk-Scoring Methods: Implications for State Medicaid Agencies

Shailesh Divey, University of Oregon, Eugene, OR, United States, Nickolas Freeman, Dwight Lewis, Jason Parton

State Medicaid agencies rely on risk-scoring methods to project costs, budget, and identify high-cost categories that can be targeted for preventative interventions. Currently, many risk-scoring approaches exist and vary widely on the dimensions of sophistication/complexity and interpretability. For example, the popular CDPS risk-scoring method is open-source and utilizes a straightforward linear regression method to generate coefficients that can be inspected to see the impact of patient-related variables on the assigned risk score. On the other end of the spectrum, the proprietary MARA model has been shown to offer more accurate risk-score estimates, however, it offers little with respect to interpretability. Using data from Alabama Medicaid collected over three years (2016–2018), this research investigates options for risk-scoring that span the spectrum of sophistication and interpretability. Insights from this research can inform decision-makers regarding the tradeoffs that arise among these two dimensions. We conduct experimentation on feature choices that provide insight regarding the impacts of feature engineering and feature selection on resulting models. Ultimately, the insights gained from Medicaid risk-scoring models can be leveraged to allocate resources effectively and improve healthcare access for underserved communities.

3 - Assessing the Equitable Distribution of Naloxone Locations

Melika Jahan Beikloo, Clemson University, Clemson, SC, United States, Mary Beth Kurz, Bryan Lee Miller, Thomas Sharkey, Chelsea Spence

The opioid epidemic remains a critical public health concern, with South Carolina (SC) experiencing its share of fatal consequences, including high rates of opioid overdose deaths. In this study, we employ Geographic Information Systems (GIS) and regression analysis to investigate the equitable access to naloxone, a crucial opioid overdose reversal medication, focusing on the most affected counties in SC.

Utilizing GIS, we spatially analyze the distribution of naloxone resources relative to opioid overdose hotspots, identifying potential disparities in access. Additionally, we employ regression modeling to assess the relationship between naloxone distribution and opioid overdose death rates. By incorporating variables such as income, demographics, population density, and healthcare access, our regression analysis seeks to explore the drivers of naloxone access and overdose outcomes.

This study aims to provide insights into the equity of naloxone distribution in addressing the opioid crisis, particularly in areas with the greatest need. Findings from this research can inform evidence-based interventions and policy initiatives to promote equitable access to naloxone and reduce opioid-related harms in SC communities.

4 - Balancing Enforcement and Access in Prescription Drug Networks via Multi-Objective Optimization

Monika Tomar, Purdue University, West Lafayette, IN, United States, Abhishek Ray, Mario Ventresca

The burgeoning crisis of prescription drug misuse, particularly opioids, poses complex challenges that intersect public health, criminology, and network science. Prescription drug networks operate within a dual paradigm, serving both legitimate medical needs and facilitating illicit drug diversion. This duality necessitates a nuanced approach to intervention, aiming to dismantle harmful activities without disrupting the legitimate supply chain essential for patient care. Drawing upon insights from deviant behavior into drug diversion dynamics and practices for harm reduction, this paper examines the intricate balance between enforcing drug misuse prevention and ensuring uninterrupted access to necessary medications. We propose a multi-objective combinatorial decision-making framework that prioritizes node removal by targeting key nodes whose removal would maximally disrupt illicit activities with minimal impact on legal drug distribution and patient access. The paper offers a detailed formulation of a combinatorial decision problem keeping in mind the interaction of intervention actions over a network of suppliers, providers/pharmacies and patients. The paper further explores the intricate tradeoffs between the various objectives by analyzing the various pareto fronts obtained by solving the problem using evolutionary algorithms.

5 - Smarter Decisions about Drug Overdoses for a Better US: Usefulness-Focused Data Profiles and Risk Modeling from the Southern Regional Drug Data Research Center

Joshua Eyer, University of Alabama, Tuscaloosa, AL, United States, Amanda Cox

The overdose crisis is experiencing its fourth wave, characterized by a spike in deaths from opioids combined with illicit stimulants. Decision makers across sectors experience challenges in responding to this on-going crisis despite limited access to comprehensive data.

The Southern Regional Drug Data Research Center (DDRC) represents an innovative initiative funded by the Bureau of Justice Assistance to promote knowledge across affected parties in a 17-state region of the south US. Housed in the Institute of Data and Analytics in the Culverhouse College of Business at the University of Alabama, the DDRC features a multidisciplinary team who will present information about the aims and method of the project to develop a large multisource (public + proprietary) data repository and to promote the development, accessibility, and transmission of knowledge from the repository to strategic stakeholders. These include public health, public safety, community organizations, nonprofits, journalists, students, and academic researchers.

The project integrates high-value public datasets (e.g., CDC, NIBRS, US Census, ARCOS) and facilitates their use for research at various levels. Educational materials and efforts will enhance research communication to promote users' ability to utilize results. DDRC analytic reports will provide innovative insights, bridging state boundaries and synthesizing data from disparate sources. An important aspect of this work and presentation will be efforts to develop substance use risk metrics for the region, complementing county-level profiles generated for our public-facing website and on-demand analytic reports. Attendees will learn how we developed the DDRC, what data we share, and how to use available resources.

6 - Addressing the Challenges of Mining Patient Data from a Procurement Perspective

Stella Hua, Western Washington University, Bellingham, WA, United States

The analysis of big patient data provides enormous healthcare benefits such as increased diagnosis accuracy and improved treatment efficiency. However, the analysis of big patient data also draws criticism from the public and poses challenges for healthcare agencies and IT vendors. This study reviews the procurement processes of several cases involving large scale healthcare data mining. The goal is to identify preventive measures that procurement needs to undertake to help address these criticisms and challenges. These preventive measures add to the dimension of procurement maturity in the procurement literature and provide insights for healthcare providers pursuing data mining services.

Design and Optimization for Transit Systems

Contributed Session

Chair: Mehr Sadat Salami, North Carolina State University

1 - Nonparametric Compressed Learning of Dynamical Systems

Boya Hou, University of Illinois,Urbana-Champaign, Urbana, IL, United States

Autonomous systems are just around the corner. Different from ``automated'' agents that operate in a fixed world, ``autonomous'' ones should be able to conceptualize, reason, and act in changing environments without human intervention. Fulfilling such an ambition requires ways to understand the environmental landscape. Under purely data-driven approaches that passively adapt to environments, agents fail to leverage previously learned knowledge and need to solve the problem from scratch every time the environment changes. The mature field of systems theory has enabled the success of model-based decision-making. Yet model identification typically requires fitting parametric models to data from interaction with the environments. In this talk, I will discuss an operator-theoretic approach to learning compressed representations of nonlinear dynamics from data with provable guarantees. We first build an analytically tractable representation of system dynamics via the conditional mean embedding operator that interacts with a reproducing kernel Hilbert space (RKHS). Compared with neural networks, kernel methods are theoretically easier to analyze, easily implementable, and demonstrate excellent empirical performance in data-limited regimes. Still, the scalability often suffers with larger datasets. To counter this difficulty, we allow selective loss in the representation of that operator to control model complexity. I will discuss sample complexity guarantees to learn such operators in centralized and decentralized settings and present applications to reinforcement learning, power system transient stability analysis, and uncertainty propagation.

2 - factors Impacting the interaction of autonomous and legacy vehicles

Roohollah Jahanmahin, Wayne State University, Detroit, MI, United States, Sara Masoud

The coexistence of autonomous vehicles (AVs) and legacy vehicles (LVs) marks a pivotal moment in the evolution of transportation. AVs, empowered by advanced technologies like sensors and artificial intelligence, offer the promise of safer and more efficient roads by reducing human error. However, with legacy vehicles primarily operated by humans, it is imperative to foster harmonious coexistence and devise strategies for their seamless interaction. This necessitates careful consideration of how AVs integrate with LVs and existing infrastructure, addressing regulatory, safety, and ethical concerns. This study delves into the dynamics between AVs and LVs using an immersive driving simulator that merges the DReyeVR project with the Carla simulator. Leveraging virtual reality through HTC Vive Pro Eye, the research emulates a first-person maneuverable ego-vehicle equipped with eye-tracking and immersion enhancements. Extensive datasets capturing real-time eye-tracking metrics and vehicle control inputs enable a convolutional neural network (CNN) model to analyze and forecast driver intention and decision-making behavior. The insights garnered, including crucial gaze patterns and driver focus, deepen our understanding of trust and safety perceptions regarding AVs. Moreover, the study evaluates driver responses such as acceleration, braking, and lane-changing behaviors in close proximity to AVs, pinpointing key factors in driver decision-making processes. These findings aim to refine interaction strategies between LVs and Level 2 and 3 AVs, ultimately fostering the safer integration of AVs into public roadways.

3 - The Impact of Automation on Workers when Workers are Strategic: The Case of Ride-Hailing

Zicheng Wang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Saif Benjaafar, Xiaotang Yang

Motivated by the behavior of drivers on ride-hailing (individual drivers decide whether to work based on the offered wage and where to locate themselves in anticipation of future fares), we examine how the introduction of autonomous vehicles impacts the strategic behavior of human drivers and driver welfare. Specifically, we consider a setting where a ride-hailing platform deploys a mixed fleet of conventional vehicles (CVs) and autonomous vehicles (AVs). The CVs are operated by human drivers who make independent decisions about whether to work for the platform and where to position themselves when they become idle. The AVs are under the control of the platform. The platform decides on the wage it pays the drivers, the size of the AV fleet, and how the AVs are positioned spatially when they are idle. The platform can also make decisions on whether to prioritize the AVs or the CVs in assigning vehicles to customer requests. We characterize the optimal decisions of the platform and contrast those with the optimal decisions in the absence of AVs. We show there are settings where introducing AVs leads to higher wages and more drivers being hired. These results can be explained by the interplay of two counteracting effects: (1) the introduction of AVs provides the platform with an additional source of supply and renders human driver substitutable (*displacement effect*); and (2) having access to and control over AVs enables the platform to influence the strategic behavior of CVs, thereby reducing the inefficiency from self-interested behavior (*incentive effect*).

4 - Applying Autonomous Vehicle Adoption Model in Examining Customers&Rsquo; Adoption Intention of Driverless Cars

Thi Ngoc Anh Tran, Korea University, Seoul, Korea, Republic of, Daeki Kim

The increase in personal vehicle usage prompted by the COVID-19 pandemic emphasizes the potential for a transformative shift within the travel industry through the widespread adoption of self-driving autonomous vehicles (AVs). Previous research has primarily concentrated on creating models for accepting automonous vehicles in developed countries, while overlooking how moderating variables influence these models. Therefore, this research aims to construct and evaluate a theoretical model for the acceptance of autonomous vehicles, highlighting demographic characteristics, individual innovativeness, and driving behaviors as pivotal factors influencing travelers' tendency towards AV utilization. Drawing upon the Autonomous Vehicle Acceptance Model (AVAM) as a foundational framework, this study employs structural equation modeling (SEM) techniques on data gathered from 1008 respondents in Hanoi, Vietnam. Results reveal noticeable differences in the drivers of behavioral intention to embrace AVs between individuals exhibiting high and low levels of personal information technology innovativeness. Notably, the perceived performance expectancy and effort expectancy show a significant impact on attitudes toward autonomous vehicles, subsequently shaping the intention to utilize them. Furthermore, facilitating conditions emerge as a direct influencer on the propensity to adopt self-driving vehicles. The limitations of research method and implications of these findings are discussed, offering insights that may prove valuable to marketers and manufacturers in navigating the landscape of self-driving vehicle adoption.

Key words: Autonomous Vehicle Acceptance Model (AVAM), personal innovativeness, self-driving autonomous vehicle.

5 - Optimal Volunteer Management in Non-profit Settings Balancing Equity and Efficiency

Hiruni Niwunhella, North Carolina State University, Raleigh, NC, United States, Mehr Sadat Salami, Faisal Alkaabneh, Leila Hajibabai

This paper presents a pioneering solution to the vehicle routing problem with pickups and deliveries with equity (VRPPD-e) within the realm of non-profit food distribution. With a focus on multiple volunteers at service centers helping with food deliveries to food-insecure households through food banks, a mixed integer programming model is developed that aims to optimize volunteer assignments, plan cost-efficient routes for their pickups and drop-offs at service centers and back, and ensure equitable service distribution. Considering each volunteer’s time window and vehicle capacity, we aim to maintain a balance among these key factors. We present a scalable solution utilizing a branch-and-price algorithm. This approach transforms the proposed model into a set partitioning problem as a relaxed linear program. The algorithm dynamically refines solutions by iteratively introducing variables. Leveraging the power of branch and price, coupled with column generation, the proposed solution technique systematically enhances the linear programming relaxations. To further optimize the column generation process, we employ a labeling algorithm. This additional step contributes to the effectiveness of our approach, providing a comprehensive strategy for solving complex optimization problems efficiently. This integrated methodology not only redefines the VRPPD-e paradigm but also provides a novel solution to workforce management challenges in the non-profit sector. The preliminary experiments highlight the algorithm’s effectiveness in optimizing volunteer assignments and vehicle routing, emphasizing considerations of fairness and cost under time-window constraints and vehicle capacity restrictions.

Methods for Traffic Monitoring

Contributed Session

Chair: Sifa Celik, Eindhoven University of Technology, EINDHOVEN, Netherlands

1 - Vehicle Routing Problems Under Uncertainties: A Comprehensive Survey of Methods and Challenges

Rashid Baimukashev, SDU University, Kaskelen, Kazakhstan, Cemil Turan, Meraryslan Meraliyev, Shirali Kadyrov

This paper provides a systematic survey of Vehicle Routing Problems (VRPs) under uncertainties, focusing on the diverse uncertainties encountered and the methods used to address them. Uncertainties in VRPs arise from several factors, including variable demand, fluctuating travel times, and evolving market conditions. These uncertainties can significantly impact the efficiency and reliability of routing solutions, making effective management critical for logistics and supply chain operations. The survey classifies these uncertainties and reviews the methodologies developed to handle them, spanning exact methods, heuristic approaches, and learning-based techniques. A novel taxonomy categorizing uncertainties and solutions is introduced, aiding in the comprehensive understanding of this complex field. Furthermore, the paper discusses the practical challenges faced by practitioners and decision-makers, emphasizing the gap between theoretical research and its real-world applications. By providing a detailed evaluation of current methods and identifying areas lacking sufficient attention, this survey aims to guide future research directions and enhance the applicability of routing solutions under uncertainty.

2 - Deep Reinforcement Learning for Efficiently Solving the Electric Vehicle Routing Problem with Time Windows and Partial Recharging

Mertcan Daysalilar, University of Miami, Miami, FL, United States, Adam Meyers

Conventional research on the Electric Vehicle Routing Problem (EVRP) often relies on traditional exact optimization methods or metaheuristic approaches, which lack some flexibility to adapt to changing operational conditions and energy demands. In addition, such methods are not well-suited for large-scale routing problems or real-time solutions needed as the modern world attempts to develop nationwide charging infrastructures to support the transition from gasoline-powered vehicles to EVs. Deep reinforcement learning (DRL) has recently been proposed and has been shown to help overcome the above limitations. This study introduces a comprehensive DRL framework to tackle the EVRP with time windows and partial recharging. Implementing time windows ensures that customer demand is met in a predetermined span of time, while implementing partial recharging allows for a more flexible charging policy that can help mitigate the undesirable downtime and operational delays arising from a rigid full recharging policy. The proposed method utilizes an attention model combining a pointer network with a graph embedding layer, which allows for a stochastic policy capable of addressing the complexities of routing EVs. The model, which is trained using a policy gradient with a rollout baseline, is designed to optimize routes and charging strategies for large-scale instances. The primary objective is to evaluate the model's effectiveness in tackling large problem instances that traditional methods cannot efficiently handle. The proposed approach not only contributes to the theoretical advancements in DRL applications for logistics, but also offers practical solutions for real-world EV fleet operations.

3 - Using Connected and Automated Vehicles as Mobile Controllers in Single Lane Roundabouts

Abdullah Farabi, NC State University, Raleigh, NC, United States, Ali Hajbabaie

This study develops a mixed integer non-linear program where connected and automated vehicles (CAV) operate optimally and work as mobile controllers to guide Human Driven vehicles (HVs) through roundabouts. As HVs may incur excess delays due to a lack of safe gaps, CAVs can send accurate indications to HVs for a safe entry to the circular roundabout path. The objective function of this model is to maximize roundabout throughput while controlling the flow of vehicles so that an equitable roundabout operations is achieved. Using Frenet coordinates, the non-linear formulation is simplified to an easier-to-solve mixed integer quadratic program and a model predictive control-based solution technique is developed to optimize CAV trajectories as well as to control HV's gap acceptance behaviors in real-time. The case study results show that the new methodology outperforms conventional traffic operation at roundabouts in terms of various performance measures (e.g., delays, stops, travel times, and throughput). Besides, the proposed model ensures equity between HVs and CAVs and improves roundabout capacity significantly.

4 - Optimal Connected Automated Vehicle Control in Freeway Merge Segments through Distributed Coordination

Fahim Kafashan, North Carolina State University, Raleigh, NC, United States, Ramin Niroumand, Ali Hajbabaie

Complex road segments like freeway merge and diverge segments are critical due to their susceptibility to bottlenecks caused by lane changing maneuvers. This study develops a mixed-integer nonlinear program (MINLP) for optimizing both the longitudinal and lateral movements of connected automated vehicles (CAVs) in these critical segments. This approach uses a hybrid solution technique combining linearization, receding horizon framework, and a vehicle-level decomposition technique to manage the problem's complexity while adapting to dynamic traffic conditions effectively. The methodology is tested in various scenarios to demonstrate its applicability to real-world freeway operations. Demonstrated across various scenarios, this methodology significantly enhances operational efficiency and safety, offering a robust model for future CAV systems integration on freeways. In the merge segment, this model resulted in up to 69.82% reduction in the total travel time and more than 200% increase in average time to collision as an indicator of safety. Similarly, this model improved diverge segments' travel times and average time to collision by up to 24.91% and 250%, respectively.

5 - Efficient Real-Time CAV Trajectory Optimization at Signal-Free Intersections Using a Greedy-Based Heuristic Approach

Ramin Niroumand, Aalto University, Espoo, Finland, Fahim Kafashan, Leila Hajibabai, Ali Hajbabaie, Claudio Roncoli

This study proposes a greedy-based heuristic method to construct connected automated vehicle (CAV) trajectories at signal-head-free intersections that not only does not use a computationally expensive solver but also provides solutions in the order of milliseconds to be used in network-level trajectory optimization frameworks. This methodology constructs multiple trajectories for each CAV and selects the one with the best objective value. In addition, a platooning logic is developed to form platoons consisting of one or more CAVs based on their relative locations and operate platoons of CAVs instead of individual CAVs at a time to achieve lower delay times. The proposed greedy-based solution technique is embedded in a receding horizon framework to further decrease the complexity of the problem and address its dynamic nature. The case study results on an isolated intersection reveal that the proposed methodology is capable of solving the optimization model in under 35 milliseconds under a demand level of 1500 veh/h/lane. The proposed methodology achieves an optimality gap of 4.61% in average delay without relying on commercial solvers.

6 - The Dynamic Delayed Time Window Assignment Vehicle Routing Problem

Sifa Celik, Eindhoven University of Technology, EINDHOVEN, Netherlands, Albert Schrotenboer, Layla Martin, Tom Van Woensel

We explore the critical balance between direct and delayed communication of time windows to customers, a trade-off that significantly impacts customer service, on-time delivery, and transport costs. This paper addresses the Dynamic Delayed Time Window Assignment Vehicle Routing Problem, a complex decision-making challenge faced by service providers managing next-day deliveries. We model our model as a Markov Decision Process (MDP) with a finite time horizon. We propose three policies: Deep Controlled Learning (DCL), the Rollout Algorithm (RO) with stochastic one-step lookahead, and the Multiple Scenario Approach (MSA), modified for our problem setting. DCL, a deep reinforcement learning framework, tackles the computational challenges of large state-action spaces through approximate policy iteration, efficient state sampling, and effective dataset construction. The RO, rooted in simulation, iteratively refines the base policy by approximating the action-value function for state-action pairs, while MSA focuses on likely future scenarios to optimize decision-making. We provide novel insights into optimizing route planning and time window assignments in the context of next-day delivery services. Demand pattern and customer positioning play a crucial role in how the decisions are taken. When customers are dispersed in either in clustered or random-clustered manner across the service area, there is a noticeable increase in their waiting time for time window assignments. There appears to be a relationship between demand variability and waiting time: as demand becomes less consistent, the waiting time for customers increases. This effect is more pronounced when demand has larger mean.

Summit - 333

Agricultural Supply Chains

Contributed Session

Chair: Harol Gamez Alban, Massachusetts Institute of Technology

1 - Research on dynamic pre-sale pricing decision of fresh agricultural products

yuxiu liang, Southeast University, Nanjing City, Jiangsu Province, China, People's Republic of, Lindu Zhao

Due to the characteristics of long growth cycle, short life cycle and difficult storage of agricultural products, in order to avoid the waste of agricultural products caused by excessive planting by farmers, the pre-sale of agricultural products is worth studying. Farmers obtain order quantity according to pre-planting, so as to obtain market demand in advance, plan planting quantity and time in a targeted way, reduce production uncertainty and risk, and avoid waste caused by over-planting.

This study considers a two-level fresh supply chain system consisting of a single supplier and fresh electricity supplier. Fresh electricity supplier conducts two stages of pre-sale of agricultural products through online channels: Pre-planting pre-sale and pre-mature pre-sale, suppliers and fresh electricity suppliers jointly participate in the current sale period, fresh electricity suppliers reduce the uncertainty of consumers' valuation of agricultural products in the pre-sale period through discount pre-sale, the study considers that in order to promote the enthusiasm of consumers to buy, suppliers and fresh electricity suppliers respectively carry out corresponding value-added services and promotional efforts. Based on the risk of agricultural products planting and the uncertainty of market demand, this paper analyzes the multi-period pre-sale of agricultural products, and studies the decision-making and coordination of supply chain themes under the dynamic pre-sale model of fresh agricultural products.

2 - A Novel Approach to the Continuous Planting and Harvest Scheduling

Maksim Lalic, BioSense Institute, Novi Sad, Serbia, Nikola Obrenovic, Gordan Mimic, Miljana Markovic, Oskar Marko, Sanja Brdar, Vladimir Crnojevic, Ivan Lukovic

Among all food chain losses, post-harvest handling and storage losses are among the most prominent, particularly in less developed countries. Farmers with limited storage and processing capabilities could substantially reduce their yield overflows and consequent unnecessary waste by adopting continuous harvest strategies. Nowadays, the increase in average farmland and the number of crop varieties opens additional room for continuous harvest. However, common planting and harvesting planning practices typically treat each parcel of land in isolation, missing the opportunity of a more integrated approach that would equalize the expected yield during the harvest period, while performing harvest activities in a reduced number of weeks.

We designed an algorithmic core of an integrated decision support system tailored to assist farmers in managing their planting and harvesting activities. This algorithmic core is a composition of the three scheduling algorithms and one weather forecast processing algorithm. With their synergy, the designed system would generate schedules that facilitate continuous harvest, with crops harvested at their optimal maturity. Furthermore, the system enables dynamic adjustment of harvesting schedules based on actual weather conditions on the fields, thereby enhancing schedule reliability and introducing stability into further operational planning. Our initial results indicate that with the generated harvest schedules it is possible to reduce the total amount of yield exceeding stated storage and processing capacities.

3 - Organic Farming Transitions: a Dynamic Bioeconomic Model

Michael Meneses, Cornell University, Ithaca, NY, United States, Clare L. Casteel, Miguel I. Gómez, David R. Just, Ravi Kanbur, David R. Lee, C.-Y. Cynthia Lin Lawell

We develop a dynamic bioeconomic model of a farmer’s decisions regarding the use of synthetic compounds (e.g., synthetic fertilizers and pesticides) and the transition from conventional to organic management. Our crop production model accounts for newly documented interrelationships among synthetic compound use, soil health, and crop yields. In particular, new insights from soil science show that the use of synthetic compounds can be harmful to beneficial soil microbes that improve agricultural yields by enhancing crop nutrient use, stress tolerance, and pest resistance. We characterize and solve for a “fully informed” farmer’s optimal synthetic compound use strategy, and for whether and how a farmer should transition from conventional to organic farming. These solutions are compared to those from a “misinformed” model in which the farmer is not aware of the interactions between synthetic compound use, soil health, and crop yields, allowing us to assess how gaining knowledge of these interactions might be expected to change farmers’ synthetic compound use strategies and, ultimately, their decisions around adopting organic management. We identify and discuss agricultural and economic conditions under which farmers can be expected to voluntarily reduce their reliance on synthetic compounds, and possibly even adopt organic management, upon learning of the benefits associated with stewardship of their soil’s microbiome. We apply our model to farmer-level pesticide-use panel data to estimate parameters governing farmers' current understanding of the interrelations between soil microbes, pesticides, and crop yields, and to examine possible effects of extension programs targeting farmers' understanding of soil microbes.

4 - Exploring Mega-Trends and Enhancing Food Supply Chain Viability: A Global Perspective

Shanshan Yang, A*STAR, Singapore, Singapore, Singapore, Xingyu Li, Wei Ye, Cheng Yin Lee, Wenda Chen, Ning Liu

The performance of food supply chains is influenced by various factors, including seasonal demand variations, perishability, geopolitics conflicts, economic conditions, external disruptions, and regulatory changes, which collectively shape market trends and supply chain dynamics, and pose challenges to managing supply chain viability. For instance, seasonal demand shifts and economic fluctuations can strain inventory levels and logistics capacities, while geopolitical conflicts can disrupt material and ingredient supplies and increase risk exposure. Understanding mega-trends in food supply chains is crucial for gauging demand and mitigating material shortages and production disruptions.

This study aims to identify global mega-trends and their complex interactions across diverse industrial sectors and geographical regions. Leveraging the Purdue GTAP database, a base model of the global food supply chain network is constructed, encompassing demand profiles, production capabilities, and supplier-buyer relationships. Subsequently, leveraging the Mintel database, regional and sectoral food market trends are systematically analyzed, elucidating their interconnections within the constructed supply chain network. By harnessing the insights gleaned from identified mega-trends, food supply chain vulnerabilities across temporal, geographical, and industrial contexts will be evaluated under various disruption scenarios. The ultimate objective is to equip the decision-maker with the requisite knowledge to proactively navigate mega-trends and disruptions. In an industrial use case, we will demonstrate how to incorporate identified mega-trends with internal operational data, tailoring specific plans to assist companies in enhancing their operational resilience, identifying alternative products and suppliers, building redundancy, and improving demand forecasting, all of which contribute to sustained viability amid the dynamics of global supply chains.

5 - Digital Technology-Enabled Quality Bunching and Financing in Agricultural Supply Chains

Penghui Guo, School of Management,Xi'an Jiaotong University, Xi'an 710049, China, People's Republic of, Gengzhong Feng, Kai Wang

Platforms are increasingly involved in agricultural supply chains (ASCs) by providing digital technology (DT) to guide farming cooperatives' operations from the initial planting stage and by offering financing services to support agricultural production. Due to the intrinsic uncertainty in agricultural product growth, the distinctive feature of DT that we capture in ASCs, which differs from existing studies on its role in improving product quality homogeneously, is clustering agricultural product quality ranges by real-timely monitoring cultivations, i.e., the quality bunching effect. To explore how the interactions between DT implementation and platform financing affect ASC participants' decisions, we consider an ASC containing a farming cooperative and a platform that procures agricultural products and sells them to online customers. Intuitively, as the quality bunching effect increases, the high-quality aggregation of agricultural products can encourage the platform's DT provision due to increased consumer consumption. Surprisingly, we find that the platform is willing to provide DT only when the quality bunching effect is relatively low because the increased consumption raises the farming cooperative's production financing costs, in turn increasing wholesale prices and negatively affecting the platform's profits. Interestingly, we find that the farming cooperative chooses platform financing even though it faces a bank interest rate that is lower than the platform interest rate. Finally, we identify the equilibrium results for DT implementation and financing strategy and provide several extensions to consolidate our conclusions. Our findings shed light on how platforms work with farming cooperatives in agriculture digitization and financing.

6 - Optimizing Agricultural Supply Chains Using Resource-Constrained Shortest Path

Steven Formaneck, Minnesota State University Mankato, Mankato, MN, United States

The goal for most businesses is to satisfy its customers while minimizing total cost or maximizing profit. Other goals such as sustainability and risk minimization, are also common. Constraints also exist within and outside the organization that increase its costs or limit its profitability such as financial budgets, scarcity of raw materials, labor, time, and production capacity. The research provides a framework for empirically deciding what organizational decisions should be made within an agricultural organization's supply chain and in what sequence to optimize profitability given its resource constraints. The research accomplishes this through a comparative study of the leading algorithms for the resource-constrained shortest path and organizational and resource factors involved, to develop the framework. An example of the framework is provided through means of a case study.

7 - Solving a stochastic logistics network design for fresh food using a sample-average approximation

Harol Gamez Alban, Massachusetts Institute of Technology, Cambridge, MA, United States, Chris Mejia

One of the most challenging tasks in today's food industry is controlling product quality throughout the food supply chain. One of the main reasons that accelerates the spoilage of fresh food is disruptions in the supply chain network, such as poor food handling in facilities, transportation problems, handling, packaging and storage facility issues and others. Models are needed to determine the optimal supply chain configuration to maintain food freshness and, thus, reduce food waste/losses. This paper integrates food quality into the supply chain network by tracking the remaining shelf lifetime. We formulate a mixed-integer linear programming (MILP) model under uncertainty that accounts for the disruptions along the logistics network. To model and solve this problem, we use a two-stage stochastic programming with recourse and sample average approximation (SAA) method. To accelerate the convergence of the algorithm, we set up a set of valid inequalities along with a splitting procedure that speeds up the performance of the model to obtain feasible and near-optimal solutions. The resulting model is applied in an illustrative case study and can be used for planning and operating food distribution systems, considering freshness and cost. The results show that the proposed approach can achieve high-quality solutions with guaranteed performance.

Machine Learning in Finance II

Invited Session

Finance

Chair: Nan Chen, Chinese University of Hong Kong, Shatin N T, Hong Kong

1 - Aico: Model-Agnostic Feature Significance Tests for Supervised Learning

Kay Giesecke, Stanford University, Stanford, CA, United States

Supervised learning algorithms are increasingly being used to guide economic and social decisions. The opaqueness of these algorithms is a key challenge, especially in highly regulated domains including financial services, where transparency is crucial. This paper provides statistical tools to improve model transparency. We develop a family of hypothesis tests for testing the significance of the input features (variables) of a supervised learning algorithm. The key idea is to evaluate a feature's incremental effect on model predictive or decision performance, relative to a baseline that does not permit variability of any feature. A null-feature's incremental effect has a distribution across a test sample whose center is non-positive. This formulation leads to simple, assumption-light uniformly most powerful sign and other tests that deliver exact, non-asymptotic p-values. These tests are model-agnostic and apply to any regression or classification model, including ensembles. They do not require retraining or other computationally costly procedures. A byproduct of the tests are interpretable measures of feature importance including exact confidence intervals that are robust to correlation among features. A hierarchical formulation can discover higher-order structure tied to subsets of features including feature interactions. A simulation study is used to demonstrate the performance of our tests and alternative approaches. An empirical study tests feature significance for a deep learning ensemble model of US home prices.

2 - Multi-task Dynamic Pricing in Credit Market with Contextual Information

Renyuan Xu, University of Southern California, Los Angeles, CA, United States, Adel Javanmard, Jingwei Ji

We study the dynamic pricing problem faced by a broker that buys and sells a large number of financial securities in the credit market, such as corporate bonds, government bonds, loans, and other credit-related securities. One challenge in pricing these securities is that most are infrequently traded, resulting in insuf-
ficient data for individual pricing. However, these products often have more structural features to utilize. To address this, we propose a multi-task dynamic pricing framework with learning, which exploits the shared structures across different securities to enhance pricing accuracy. Our approach consists of two stages: an initial regression using aggregated data across securities, followed by a refined estimation for each individual security. Theoretically we characterize the regret of our policy, which is better than both a policy that treats each security individually and a policy that treats all securities as the same. Empirical results on financial datasets show that our framework achieves better performance compared to benchmark methods.

This is based on joint work with Adel Javanmard and Jingwei Ji (USC).

3 - On Consistency of Signature Using Lasso

Chaoyi Zhao, Peking University, Beijing, China, People's Republic of, Xin Guo, Binnan Wang, Ruixun Zhang

Signatures are iterated path integrals of continuous and discrete-time processes, and their universal nonlinearity linearizes the problem of feature selection in time series data analysis. This paper studies the consistency of signature using Lasso regression, both theoretically and numerically. We establish conditions under which the Lasso regression is consistent both asymptotically and in finite sample. Furthermore, we show that the Lasso regression is more consistent with the Itô signature for time series and processes that are closer to the Brownian motion and with weaker inter-dimensional correlations, while it is more consistent with the Stratonovich signature for mean-reverting time series and processes. We demonstrate that signature can be applied to learn nonlinear functions and option prices with high accuracy, and the performance depends on properties of the underlying process and the choice of the signature.

Recent advances in Choice Modeling

Invited Session

Revenue Management and Pricing

Chair: Ashwin Venkataraman, University of Texas at Dallas, Richardson, TX, United States

1 - Assortment Optimization with Visibility Constraints

Marouane Ibn Brahim, Cornell University, New York, NY, United States, Théo Barré, Omar El Housni, Andrea Lodi, Danny Segev

Motivated by applications in e-retail and online advertising, we study the problem of assortment optimization with visibility constraints, termed AOV. Given a universe of substitutable products and a stream of T customers, the objective is to determine the optimal assortment of products to offer to each customer in order to maximize the total expected revenue, while ensuring an exogenously-given minimum display requirement, referred to as visibility constraints. We assume that customer choices follow a Multinomial Logit model. We provide a characterization of the structure of the optimal assortments and present an efficient polynomial time algorithm for solving AOV. Our algorithm leverages the supermodularity of a novel function called "expanded revenue" of an assortment. Additionally, we demonstrate that AOV can be formulated as a compact linear program. Next, we consider AOV with cardinality constraints, which we prove to be strongly NP-hard and not admitting an FPTAS, even when all products have identical prices. Subsequently, we devise a PTAS for AOV under cardinality constraints with identical prices. Our algorithm linearizes the objective function through a carefully crafted guessing procedure, then solves the linearized program, and randomly rounds its solution to derive a near optimal solution. We also examine the revenue loss due to visibility constraints, and we propose a strategy to distribute the loss among the products subject to visibility constraints. Each vendor is charged an amount proportional to their product's contribution to the revenue loss. Finally, we present the results of our numerical experiments providing illustration of the obtained outcomes.

2 - Assortment and Price Optimization Under an Endogenous Context-Dependent Multinomial Logit Model

Yicheng Bai, Amazon, New York, NY, United States, Omar El Housni, Paat Rusmevichientong, Huseyin Topaloglu

Motivated by empirical evidence that the utility of each product depends on the assortment of products offered along with it, we propose an endogenous context-dependent multinomial logit model (Context-MNL) under which the utility of each product depends on both the product's intrinsic value and the deviation of the intrinsic value from the expected maximum utility among all the products in the offered assortment. Under the Context-MNL model, an assortment provides a context in which customers evaluate the utility of each product. Our model generalizes the standard multinomial logit model and allows the utility of each product to depend on the offered assortment. The model is parsimonious, requires only one parameter more than the standard multinomial logit model, captures the assortment-dependent effect endogenously, and does not require the decision-maker to determine in advance the relevant attributes of the assortment that might affect the product utility. The Context-MNL model also admits tractable maximum likelihood estimation and is operationally tractable, with efficient solution methods for solving assortment and price optimization problems. Our numerical study, which is based on data from Expedia, shows that compared to the standard multinomial logit model, the Context-MNL model substantially improves out-of-sample goodness of fit and prediction accuracy.

3 - A Simple Way Towards Fair Assortment Planning: Algorithms and Welfare Implications

Wentao Lu, Carey Business School, Johns Hopkins University, Baltimore, MD, United States, Ozge Sahin, Ruxian Wang

Traditional assortment optimization creates unfairness among sellers as only a single assortment with the highest expected revenue is chosen resulting in some sellers being excluded from recommendations or assortments, with minimal market exposure and revenue. To address this issue, we incorporate fairness constraints that ensure fair market exposures for all sellers. These constraints ensure each seller to have a minimum market exposure, which may depend on the seller's reputation, product quality, and price, among other features. We show that the optimal solution with fairness constraints is to randomize over at most n nested assortments, where n is the number of sellers (or products), and the optimal solution can be found in polynomial time. For cases in which there are other business constraints including imposing cardinality constraints on the assortments and limiting the number of different assortments, we characterize the structure of the optimal solutions and propose efficient heuristics. We further investigate the impact of fairness constraints on consumer welfare, and show that it always increases when such constraints are imposed. Our analysis reveals that when fairness constraints induce new sellers with high quality products to enter the platform, all involved parties are better-off resulting in a win-win-win situation. Even when there is no new seller entry, we identify cases in which the total welfare improves and therefore propose a revenue redistributing mechanism to achieve a win-win-win solution.

4 - Generalized Stochastic Preference Choice Model

Ashwin Venkataraman, University of Texas at Dallas, Richardson, TX, United States

We propose a new discrete choice model, called the generalized stochastic preference (GSP) model, that incorporates non-rationality into the stochastic preference (SP) choice model, also known as the rank-based choice model. Our model can explain several choice phenomena that cannot be represented by any SP model such as the compromise and attraction effects, but still subsumes the SP model class. The GSP model is defined as a distribution over consumer types, where each type extends the choice behavior of rational types in the SP model. We build on existing methods for estimating the SP model and propose an iterative estimation algorithm for the GSP model that finds new types by solving a integer linear program in each iteration. We further show that our proposed notion of non-rationality can be incorporated into other choice models, like the random utility maximization (RUM) model class as well as any of its subclasses. As a concrete example, we introduce the non-rational extension of the classical MNL model, which we term the generalized MNL (GMNL) model and present an efficient expectation-maximization (EM) algorithm for estimating the GMNL model. Numerical evaluation on real choice data shows that the GMNL and GSP models can outperform their rational counterparts in out-of-sample prediction accuracy.

Revenue Management and Pricing

Chair: Hongyao Ma, Columbia University, New York, NY, 10027, United States

Co-Chair: Francisco Castro, UCLA Anderson School of Management, Los Angeles, CA, United States

Co-Chair: Chiwei Yan, University of California Berkeley, San Francisco, CA, United States

1 - Computing Equilibrium for a Class of Dynamic Queueing Games

Chiwei Yan, University of California Berkeley, San Francisco, CA, United States, Francisco Castro, Hongyao Ma, Denise Cerna

We will discuss a general dynamic equilibrium solver for a class of dynamic queueing games involving strategically accepting jobs. It has wide applications in many market design applications, including kidney allocation, ridesharing matching, etc. We discuss a simple procedure for equilibrium computation and discuss its convergence properties. We showcase promising empirical results based on ridesharing airport dispatching data that uncover interesting new insights that have not appeared in our previous fluid analysis (Castro, Ma, Nazerzadeh, and Yan 2021).

2 - Who Ate the Lunch? a Variational Em Algorithm for Identifying Refund Hunters

Chenkai Yu, Columbia University, New York, NY, United States, Arpit Agarwal, Hongyao Ma

For online platforms such as UberEats and DoorDash, a central challenge in customer service is the lack of ground truth — when a customer reports that an order was never delivered, it is difficult for support agents to determine if the driver kept the food, a passer-by took the delivery, or the customer is falsely claiming a missing order. This uncertainty often results in platforms shouldering the costs for refunds, without holding either side of the market accountable. In this work, we propose a variational Expectation-Maximization (EM) algorithm for evaluating the trustworthiness of each customer and driver, considering both their frequency of platform use and the reliability of the agents (on the other side of the market) each participant interacted with. We show via simulations that our algorithm significantly improves accuracy in identifying strategic participants, compared to several baseline algorithms, including a naive method that scores each participant based only on their past defect rates.

3 - Information Sharing Effects of High Stock Delivery Windows on Online Platforms

Do Yoon Kim, Boston College, Chestnut Hill, MA, United States, Benjamin Knight, Dmitry Mitrofanov

In this paper, we analyze a novel information-sharing policy to reduce stockouts on online grocery retail platforms and thereby improve platform performance. This policy involves leveraging the digital interface of online platforms to disseminate information about delivery windows when retailer stock levels are at their peak. Ex-ante, it is unclear if such a policy would positively influence customers' purchasing patterns, particularly in terms of its impact on platforms' fundamentals. We conducted a large-scale field experiment on over 1M users on Instacart, an online grocery delivery platform. In this experiment, customers in the treatment group were prompted "Higher stock at this time" under delivery windows corresponding to peak supermarket stock levels. Interestingly, we find that this cost-free information-sharing policy significantly increased customers' conversion rates, as well as the propensity of customers to pick high-stock delivery windows. We also observe that this policy reduces item refund and replacement rates by 2.2% and 2.7%, respectively, as well as increases the platform's revenue by 6\% and the number of orders placed by 3%. Finally, treated users increase orders from stores they have not previously ordered from and order novel items, suggesting an stock information has an exploratory effect. Our findings suggest simple information sharing policies can increase customer orders, enhance their willingness to explore new products and retail partners, and potentially lead to a more significant positive long-term impact on platform fundamentals.

4 - Improving Worker Learning in the Gig Economy

Shunan Jiang, University of California, Berkeley, Berkeley, CA, United States, Park Sinchaisri

The gig economy is experiencing exponential growth, with an increasing number of workers engaging in on-demand platforms across various sectors, from grocery delivery to healthcare. These gig workers, often independent contractors, face unique challenges in their work environment as they lack structured training programs and supervision. Therefore, understanding how these workers learn and improve their performance becomes crucial. In collaboration with a grocery delivery platform, our work aims to explore the decision-making and learning processes employed by on-demand shoppers and inform the development of effective training and scheduling programs tailored to the unique needs of gig economy workers.

Revenue Management and Pricing

Chair: Yifan Feng, National University of Singapore, Singapore, Singapore

1 - Optimizing Scalable Targeted Marketing Policies with Constraints

Yuting Zhu, National University of Singapore, Singapore, Singapore, Haihao Lu, Duncan Simester

Targeted marketing policies target different customers with different marketing actions. While most research has focused on training targeting policies without managerial constraints, in practice, many firms face managerial constraints when implementing these policies. For example, firms may face volume constraints on the maximum or minimum number of actions they can take, or on the minimum acceptable outcomes for different customer segments. They may also face similarity (fairness) constraints that require similar actions with different groups of customers. Traditional optimization methods face challenges when solving problems with either many customers or many constraints. We show how recent advances in linear programming can be adapted to the targeting of marketing actions. We provide a theoretical guarantee comparing how the proposed algorithm scales compared to state-of-the-art benchmarks (primal simplex, dual simplex and barrier methods). We also extend existing guarantees on optimality and computation speed, by adapting them to accommodate the characteristics of targeting problems. We implement the proposed algorithm using data from a field experiment with over 2 million customers, and six different marketing actions (including a no action “Control”). We use this application to evaluate the computation speed and range of problems the algorithm can solve, comparing it to benchmark methods. The findings confirm that the algorithm makes it feasible to train large-scale targeting problems that include volume and similarity constraints.

2 - Choice Model Estimation with Stockout-Based Substitution in Censored Demand Processes

Longlin Wang, Harvard University, Cambridge, MA, United States, Ningyuan Chen

In brick-and-mortar retailing, shelves are stocked with multiple units of products. Customers arrive during the day and make purchases governed by a discrete choice model and stockout-based substitution. The store in many cases only has access to the inventory level of each product at the beginning and the end of the horizon, while individual decisions in the process are undisclosed. We study the identifiability of the problem and propose a method to estimate parameters of a multinomial logit (MNL) choice model in this highly censored situation. The proposed estimators are empirical risk minimizers solved by a stochastic first-order algorithm. Our work adds to the estimation perspective of prevalent MNL-based dynamic assortment planning problems. We showcase the efficacy of our method with both synthetic experiments and industry applications where our learning task indeed arises.

3 - Feature Misspecification in Sequential Learning Problems

Dongwook Shin, HKUST Business School, Clear Water Bay, Hong Kong, Dohyun Ahn, Assaf Zeevi

We consider a class of sequential learning problems, where a decision maker must learn the unknown statistical characteristics of a finite set of alternatives (or systems) using sequential sampling to ultimately select a subset of "good" alternatives. A salient feature of our problem is that system performance is governed by a set of features. The decision maker postulates the dependence on these features to be linear, but this model may not precisely represent the true underlying system structure. We show that this misspecification, if not managed properly, can lead to suboptimal performance due to a phenomenon identified as sample-selection endogeneity. We propose a prospective sampling principle—a new approach that eliminates the adverse effects of misspecification as the number of samples grows large. The proposed principle applies across a very general class of widely used sampling policies, enjoys strong asymptotic performance guarantees, and exhibits effective finite-sample performance in numerical experiments.

4 - A Behavioral Model for Multi-Armed Bandits: Theoretical Framework and Experimental Evidence

Jingying Ding, National University of Singapore, Singapore, Singapore, Yifan Feng, Ying Rong

The exploration-exploitation trade-off is a fundamental concept arising when the decision maker needs to make repeated choices, whose rewards are unknown *in priori*. This paper delves into how humans navigate this trade-off through the lens of the multi-armed bandit (MAB) problem. Inspired by both behavioral economics and online learning literature, we introduce a novel family of behavioral policies called Myopic Quantal Choice (MQC). It is a dynamic adaptation of quantal choice models, deriving anticipated utilities directly from past rewards. MQC offers a simple method to describe the arm selection process, and yet is rich enough to quantify the exploration-exploitation trade-off through a "shrinkage rate of exploration."
Through both non-asymptotic and asymptotic analysis, we show that MQC admits intuitive properties that match the qualitative patterns of the laboratory experiment data. Particularly, MQC always converges to the optimal arm, thus capturing the "learning" effect. In addition, we characterize MQC's regret in the asymptotic regime and demonstrate the effects of "over-" and "under-" exploration; Over-exploration with a too small shrinkage rate parameter results in gradual deterioration of the lower bound of regret, while under-exploration with a too large rate parameter leads to sudden deterioration. Analysis of laboratory experiment data reveals that the MQC model excels in predictive power compared to other behavioral models. Insights from the asymptotic regime also extend to the finite horizon experiments. Particularly, when we fit the MQC model to the data, a prevalent tendency toward over-exploration becomes evident.

Human-Algorithm Interactions in Behavioral Analytics

Invited Session

Revenue Management and Pricing

Chair: Yueyang Zhong, London Business School, London, N/A

1 - Learning when to Advise Human Decision Makers

Gali Noti, Cornell University, Ithaca, NY, United States, Yiling Chen

<blockquote mathjax="">Artificial intelligence (AI) systems are increasingly used for providing advice to facilitate human decision making in a wide range of domains, such as healthcare, criminal justice, and finance. Motivated by limitations of the current practice where algorithmic advice is provided to human users as a constant element in the decision-making pipeline, in this paper we raise the question of when should algorithms provide advice? We propose a novel design of AI systems in which the algorithm interacts with the human user in a two-sided manner and aims to provide advice only when it is likely to be beneficial for the user in making their decision. The results of a large-scale experiment show that our advising approach manages to provide advice at times of need and to significantly improve human decision making compared to fixed, non-interactive, advising approaches. This approach has additional advantages in facilitating human learning, preserving complementary strengths of human decision makers, and leading to more positive responsiveness to the advice.

2 - Information Aggregation In Marketplaces

Dragos Florin Ciocan, INSEAD, Fontainebleau, France

Modern marketplaces function not only as facilitators of transactions but also as information aggregators. This leads to information asymmetry where the marketplace itself may have superior knowledge of demand than the sellers transacting through it. We investigate optimal sale mechanisms in this situation.

3 - A Space-Efficient Algorithm for Counting Distinct Elements in the Turnstile Model

Tingting Ou, Columbia University, New York, NY, United States, Rachel Cummings, Alessandro Epasto, Jieming Mao, Tamalika Mukherjee, Peilin Zhong

The continual observation streaming setting captures data analysis scenarios where both data collection is ongoing, and real-time analysis of the collected data is needed at all time points. The \emph{turnstile} streaming model is a subclass of the continual observation model and allows for both the insertion and deletion of data items over time. Typically, the length of the stream T and the size of the universe $\cU$ from which data items come from are considered to be extremely large, thus practical solutions should use space at most sublinear in T and $\mathcal{U}$. Because many of the relevant applications for data analysis in the continual observation setting involve the analysis of sensitive user data, this motivates the need to develop space-efficient algorithms that achieve formal privacy protections such as differential privacy.

We give the first sublinear space differentially private algorithm for the fundamental problem of counting distinct elements in the turnstile streaming model that achieves $\Tilde{O}(T^{1/3})$ space and additive error and a $(1+\eta)$-relative approximation for all $\eta \in (0,1)$. Our algorithm significantly improves upon the space requirements of the state of the art for this problem in the turnstile model~\cite{JainKRSS23} which has a linear dependency in both T and $\vert \cU \vert$, while still achieving an additive error that is close to the known $T^{1/4}$ lower bound.

4 - Human Expertise in Algorithmic Prediction

Rohan Alur, Massachusetts Institute of Technology, Cambridge, MA, United States

We introduce a novel framework for incorporating human expertise into algorithmic predictions. Our approach focuses on the use of human judgment to distinguish inputs which `look the same' to any feasible predictive algorithm. We argue that this framing clarifies the problem of human/AI collaboration in prediction tasks, as experts often have access to information---particularly subjective information---which is not encoded in the algorithm's training data. We use this insight to develop a set of principled algorithms for selectively incorporating human feedback only when it improves the performance of any feasible predictor. We find empirically that although algorithms often outperform their human counterparts *on average*, human judgment can significantly improve algorithmic predictions on *specific* instances (which can be identified ex-ante). In an X-ray classification task, we find that this subset constitutes nearly 30% of the patient population. Our approach provides a natural way of uncovering this heterogeneity and thus enabling effective human-AI collaboration.

Economic Decision-Making: Games and Simulations

Contributed Session

Chair: Guilherme Tortorella, University of Melbourne, Docklands, Australia

1 - An Experimental Investigation of Bounded Rationality of a Newsvendor Under Supply Shortages

Anannya Gogoi, Rajagiri Business School, Kochi, India, Ashutosh Sarkar

This study aims to examine how retailers react to supply disruptions, which contribute to additional complexity during inventory decision-making. We explore the shortage gaming exhibited by retailers in a single supplier and multiple retailers supply chain. We conduct a between subjects behavioral experimental game to capture the retailer's sub-optimal decision-making under uncertain supply shortages with four experimental sessions. The experimental sessions were in a 2 (capacity uncertainty) X 2 (magnitude of disruption) factorial design. We adopt the Quantal Response Equilibrium (QRE) framework to explain the behavioral irregularities. Our results reveal the presence of bounded rationality in retailers during decision-making under supply disruption across all the treatment conditions. The results show that supply disruption significantly affects retailers' ordering behavior. The probability of supply disruption affects the ordering decisions significantly. Finally, we discuss how these results may help researchers and practitioners better understand retailers' ordering behavior and provide implications considering disruptions at the supplier's end.

Keywords: *Behavioral operations, Experiments, Newsvendor model, Shortage gaming, Supply disruption.*

2 - A Gameful Learning Approach in Engineering Economics

Esra Agca Aktunc, Rensselaer Polytechnic Institute, Troy, NY, United States

An undergraduate Engineering Economics course is redesigned with gameful and active learning interventions to increase student engagement and achieve higher-level learning outcomes including analysis, synthesis, and evaluation. The main additional activities are CasePlays which are case studies that require collaborative problem solving and in-person role-playing from teams of students. CasePlays include tasks of formulating cash flows, evaluating alternatives based on performance measures such as rate of return, carrying out cost-benefit analysis, replacement analysis, sensitivity analysis, or portfolio analysis, and making recommendations. CasePlays involve random disruptions and require discussions among different stakeholders such as project managers, investors, government regulators, or environmental activists. Students are expected to consider ethical, environmental, sustainability, and societal factors in decision making as a team. Following the in-person activity, students are expected to reflect on their learning experience through an individual written response. The assessment strategies are modified by using rubrics and changes in grading policies. The student performance results, feedback, and observations based on a pilot study of the redesigned course will be presented.

3 - A Card Game for Teaching TCE-Based Make-or-Buy Decisions

Beverly Osborn, Indiana University, Indianapolis, IN, United States

I developed this card game to use in the make-or-buy section of my in-person class on global sourcing. It gives students an opportunity to discover and discuss concepts of asset specificity, opportunism, bargaining power, signaling, contract management and incomplete contracts. I will demonstrate the game, share my teaching materials, and request feedback. If time and attendance allow, we will play a round of the game during the session.

TCE Card Game Overview: Each student is assigned the role of either a buyer or a supplier. Students play the game in buyer-supplier pairs and aim to earn as many points as possible. Buyers compete only against other buyers, and suppliers compete only against other suppliers. Each player's decisions affect both their own points and the points of their supply chain partner. Opportunistic behavior tends to arise in line with theoretical predictions.

4 - Artificial Intelligence and Quality Management

Guilherme Tortorella, University of Melbourne, Docklands, Australia, Daniel Nascimento

This study empirically examines the effects of artificial intelligence (AI) integration into quality management (QM) processes of service organizations. A multi-case study in service organizations of different types was conducted. We utilized multiple sources of evidence to analyze and triangulate findings, yielding the development of propositions in light of the Dynamic Capabilities theory. Our findings indicated that AI adoption positively supports QM, especially in terms of the organization's ability to quickly learn and create new quality control and assurance solutions/procedures from this learning (sensing), and to integrate them into organizational processes and routines (seizing). The identification of the impact of AI adoption on QM helps service organizations anticipate potential issues and address adequate countermeasures to reinforce their QM processes towards superior performance results.

Innovative Decision-Making in Dynamic Environments: Trends and Applications

Invited Session

Decision Analysis Society

Chair: Zheng Zeng, Rutgers University, East Brunswick, NJ, United States

1 - Drivers of Reshoring and Offshoring Decisions in the Life Sciences Industry

Aman Goswami, Rutgers Business School, Newark, NJ, United States, Alok Baveja, Esther Ho, Lian Qi, Jing Wang

Reshoring and offshoring are considered strategic approaches to sourcing and managing production operations, offering significant benefits to a firm's operations, costs, and risks. In this research, we examine the joint drivers of reshoring and offshoring decisions for life sciences firms based in the USA. This research develops a conceptual framework based on extant literature and compiles empirical panel data curated from secondary sources. We propose and validate hypotheses with models that link economic factors (e.g., GDP), firm-specific factors (e.g., tax rates), industry-specific factors (e.g., industry type), and risk factors (e.g., exchange rate fluctuations) to reshoring and offshoring decision-making. Further, the amount of capital investment and projected jobs resulting from such decisions are also analyzed. Our findings uncover the importance of the overall economic development, market size, purchasing power, and the cost of doing business in a country as important drivers of reshoring and offshoring decisions. We also find that the firm size moderates the reshoring and offshoring decision-making, with larger firms presenting stronger reshoring capabilities.

2 - O2O On-Demand Delivery: Order Assignment with Behavior Heterogeneity of Crowd-Sourced Drivers

Xinyi Huang, University of Iowa, Iowa City, IA, United States, Tonghua Lin, Weiwei Chen, Hongyan Dai

Online-to-Offline (O2O) on-demand services, such as food and grocery delivery platforms, enable customers to place orders online and receive their products offline shortly thereafter. O2O customers typically have high expectations for delivery times, leading many platforms to rely heavily on crowdsourced drivers for order fulfillment. However, these platforms often fail to recognize the heterogeneity of drivers and neglect to consider their varying routing preferences. Therefore, the algorithm might mismatch the drivers' capacities with the complexities of orders and ignore the drivers' local knowledge. We have also observed disparities between drivers' assigned routes and their actual routing choices in our data. We aim to integrate routing predictions into our optimization. By incorporating the learned heterogeneity of crowdsourced drivers, we intend to enhance the order assignment and sequencing algorithm. Our ultimate goal is to establish a "human-in-the-loop" framework that aligns the algorithm with real-world scenarios, enabling a more effective balance between algorithms and human input.

3 - SpatialRank: Urban Event Ranking with NDCG Optimization on Spatiotemporal Data

Bang An, University of Iowa, Iowa City, IA, United States, Xun Zhou

The problem of urban event ranking aims at predicting the top-k most risky locations of future events such as traffic accidents and crimes. This problem is of fundamental importance to public safety and urban administration especially when limited resources are available. The problem is, however, challenging due to complex and dynamic spatio-temporal correlations between locations, uneven distribution of urban events in space, and the difficulty to correctly rank nearby locations with similar features. Prior works on event forecasting mostly aim at accurately predicting the actual risk score or counts of events for all the locations. Rankings obtained as such usually have low quality due to prediction errors. Learning-to-rank methods directly optimize measures such as Normalized Discounted Cumulative Gain (NDCG), but cannot handle the spatiotemporal autocorrelation existing among locations. In this paper, we bridge the gap by proposing a novel spatial event ranking approach named SpatialRank. SpatialRank features adaptive graph convolution layers that dynamically learn the spatiotemporal dependencies across locations from data. In addition, the model optimizes through surrogates a hybrid NDCG loss with a spatial component to better rank neighboring spatial locations. We design an importance-sampling with a spatial filtering algorithm to effectively evaluate the loss during training. Comprehensive experiments on three real-world datasets demonstrate that SpatialRank can effectively identify the top riskiest locations of crimes and traffic accidents and outperform state-of-art methods in terms of NDCG by up to 12.7%.

4 - Patient-Centric Appointment Scheduling Considering Patient Heterogeneity

Chenhao Zhou, Rutgers Business School, Newark, NJ, United States, Weiwei Chen, Xin Ding, Lei Lei

Deterministic models traditionally used for resource allocation are inadequate for the practical realities of scheduling chemotherapy outpatient visits, particularly at the Cancer Institute of New Jersey (CINJ), where patient preferences and appointment timings can vary unpredictably. This limitation necessitates a more sophisticated approach that accommodates inherent variability and uncertainty in patient scheduling. This research proposes a two-stage scheduling approach designed to address these limitations, aiming to enhance both patient satisfaction and operational efficiency by incorporating patient preferences and real-time resource availability.

In Stage I, a recommender system is introduced to assign patients to their preferred appointment windows during the call. This stage balances operational efficiency with patient uncertainties through three key components: Patient Late/Early Identification, which uses historical data to predict the likelihood of patients arriving as scheduled; Waiting Time Prediction, which estimates wait times from patient check-in to treatment initiation to recommend optimal time windows; and a Model-based Recommender System utilizing deep reinforcement learning to dynamically adjust recommendations based on ongoing patient bookings and resource availability.

Stage II involves refining the allocation of specific timeslots within the preferred windows as the appointment date approaches. This phase employs a stochastic model to adapt to last-minute changes and uncertainties, representing a significant advancement over the deterministic model previously used. By addressing the dynamic and uncertain nature of appointment scheduling at CINJ, this research aims to enhance patient satisfaction and operational efficiency, ultimately improving the alignment between patient needs and resource availability.

5 - An Empirical Study on the Impact of Social Media User-Generated Policy Narratives on Citizen Engagement Behaviors

Min Zhang, Communication University of China, Beijing, China, People's Republic of, Fei Wang

The importance of citizen engagement in policy communication has grown with the advent of social media, which offers novel avenues for public interaction that transcend traditional media limitations. In this context, the study investigates the transformative potential of personalized policy narratives on social media platforms to engage the public more deeply in policy discourse. This study examines the impact of personalized policy narratives on public engagement through social media, challenging the traditional focus on standardized narrative content within the narrative policy framework. Using narrative transportation theory, the research analyzes 10,577 short videos from the Douyin platform related to new energy vehicle policies. Employing a combination of deep learning, dictionary-based approaches, and manual coding, the study identifies three key characteristics of policy narratives: cognitive embedding, affective embedding, and reference embedding. It explores how these characteristics influence public participation behaviors—specifically likes and shares—and examines the moderating effects of policy type and narrator influence. The findings reveal that each narrative characteristic differentially impacts engagement, with contextual factors significantly shaping these effects. This paper contributes to narrative policy studies by introducing advanced methodologies for analyzing large-scale social media data and provides new insights into the role of personalized narratives in enhancing public engagement with policy issues.

Decision Models for Network Security and Resilience

Invited Session

Decision Analysis Society

Chair: Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA, United States

1 -

Strategic Coordination of Heterogeneous Resources for Attack Detection

Pichamon Anukulkarnkusol, Georgia Institute of Technology, Atlanta, GA, United States, Mathieu Dahan

We study a two-player network inspection game in which the defender coordinates sensors with potentially heterogenous detection capabilities to detect attacks placed by a strategic attacker. We assume that there are multiple types of sensors, each determined by the detected area coverage when placed at each detector location. The objective of the defender (resp. attacker) is to minimize (resp. maximize) the expected number of undetected attacks. We analytically characterize Nash equilibria of this zero-sum game in scenarios where there is no overlapping detected area coverages upon placing sensors at any detector location, and both players possibly perform a randomized strategy. We then introduce a new solution approach derived from our analysis and validate its efficacy through computational experiments.

2 - Strategic Allocation of Heterogeneous Resources for Network Security

Bobak McCann, Georgia Institute of Technology, Atlanta, GA, United States, Mathieu Dahan

We consider a network inspection game, in which a defender positions heterogeneous detectors according to a probability distribution in order to detect multiple attacks caused by a strategic attacker. We assume the defender has access to multiple types of detectors that can potentially differ in their accuracy and cost, and that the attacker has access to multiple types of attack units that can potentially differ in their effectiveness. The objective of the defender (resp. attacker) is to minimize (resp. maximize) the expected number of undetected attacks. We provide a polynomial algorithm to compute Nash Equilibria for this game under the assumption that each component in the network can be monitored from a unique detector location.

3 - Generalization bounds for sequential time-series and supply chain decision models

William Zhang, MIT Operations Research Center, Cambridge, MA, United States, Saurabh Amin, Georgia Perakis, Aron Brenner

Supply chain analytics often involves forecasting quantities (such as demand or supply of critical parts) for the purpose of deciding order quantities or for pricing over a time horizon. Here we consider a predict-then-optimize (or sequential learning and optimization) setting in which nested time-series models are learned based on multi-source contextual data, including macroeconomic indicators correlated with supply chain performance indicators. We develop new generalization bounds that account for two key characteristics: (1) Differences in the data availability of various contextual features and structural relationships; (2) Impact of forecasting accuracy on downstream decisions. We develop new generalization bounds by leveraging statistical properties of strong mixing processes and stability of learning algorithms for this setting. Our results combine and extend prior work in both generalization bounds for non-iid data and predict-then-optimize problems. We illustrate using classical examples such as the newsvendor problem and two-stage least squares. We also highlight implications for model selection for demand forecasting and pricing decisions for auto industry.

4 - Military Logistics Planning for Expeditionary Warfare

J. Haden Boone, Georgia Institute of Technology, Atlanta, GA, United States, Matthew Ford, Samuel Tan, Mathieu Dahan, Peter Frazier, Yongjia Song, Huseyin Topaloglu

Problem definition: In times of geopolitical instability, the United States Marine Corps (USMC) may be required to quickly deploy expeditionary forces to contested areas. We develop a decision-support tool that designs military logistics plans for supporting flow and sustainment of such forces in expeditionary environments. ***Methodology:*** We propose a scheduled service network design model to optimize the routing and scheduling of various transportation vehicles (connectors) and commodities across an intermodal expeditionary logistics network. Formulated as a mixed-integer program (MIP), the objective of this model is to minimize penalties incurred for late force closure and fulfillment of demand, while accounting for connector capacities, speeds, and ranges, as well as the availability of commodities. ***Results:*** We illustrate the application of our model through a fictitious warfare scenario set in Southern California designed to reflect USMC training scenarios. Our results highlight the effectiveness of the proposed MIP in creating complex intermodal logistics plans to ensure timely fulfillment of expeditionary demands. This framework offers the first optimization-based decision-support tool for expeditionary logistics planning, contrasting with the current qualitative analyses conducted by military logistics planners. Our findings provide the USMC with valuable granular and aggregated insights into the efficiency and vulnerability of their logistics network.

5 - Dynamic Operational Planning in Warfare: A Stochastic Game Approach to Military Campaigns

Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA, United States, Joseph McCarthy, Chelsea White

We study a two-player discounted zero-sum stochastic game model for operational planning in military campaigns. At each stage, the players manage multiple commanders who order military actions on objectives that have an open line of control. When a battle occurs to determine control of an objective, its stochastic outcome depends on the actions and the enabling support provided by the control of other objectives. Each player aims to maximize the cumulative number of objectives they control, weighted by their criticality. To solve this large-scale stochastic game, we derive properties of its Markov perfect equilibria, significantly reduce state and action spaces, and accelerate Shapley's value iteration algorithm by eliminating dominated actions. We demonstrate the computational value of our equilibrium results on a case study that reflects representative operational-level military campaigns with geopolitical implications. Our analysis reveals a complex interplay between the game's parameters and dynamics in equilibrium, resulting in new military insights for strategic leadership.

Emerging Technology and Decision Analysis

Invited Session

Decision Analysis Society

Chair: Qian Jia, Nanjing University, Nanjing, N/A

1 - Leveraging User Intent Extraction to Enhance Search Recommendation Efficacy in Online Shopping Platform

Li Lin, Nanjing University Business School, Nanjing, China, People's Republic of, Qianzhou Du, Alan Wang, Wenqi Shen

In the digital era, an increasing number of consumers are turning to online shopping platform for their daily needs, highlighting the imperative to comprehend consumer behavior. To assist in this endeavor, online shopping platform leverage query-based search systems in their apps, enabling customers to effortlessly locate information and products that meet their preferences. However, previous studies have rarely explored the role of user intent extraction in enhancing the effectiveness of these queries. We propose a novel deep learning model that initially classifies user queries based on their intent, distinguishing between informational and navigational purposes. Following this intent classification, we construct an improved two-tower model tailored to these distinct user intents. We validate our model using search history and click data from a renowned Chinese online shopping Platform RT-Mart. The analysis confirms that recognizing different user intents notably improves Hit Rate and Normalized Discounted Cumulative Gain(NDCG) . Finally, we demonstrate the scalability of our framework and identify the set of optimal features that maximizes accuracy.

2 - Empowering Content Creators to Add Link to Competing Platforms: a Blessing or Curse?

Jianchao Sheng, University of Science and Technology of China, Hefei, China, People's Republic of, Jianqing Chen

The digital content industry is experiencing rapid growth, with numerous platforms hosting an extensive type of content generated by independent creators. A primary revenue stream for these platforms is advertising, contingent upon the number of active customers viewing the content. The conventional advice is to raise barriers to protect consumers from competitive poaching. However, we see instances that appear to contradict this advice. One such practice is when Instagram allows its content creators to add link to competitive digital content platforms, including TikTok. In this paper, we develop a game-theoretic model to examine whether and under what conditions empowering creators to add link to competing platforms can be a beneficial strategy. We analyze two competing digital content platforms, a representing creator, and a mass of consumers. We find that when the advertising fee is too high or too low, neither platform chooses to allow creators to add link in equilibrium. Otherwise, at least one platform chooses to allow such behavior. Interestingly, when the advertising fee is moderately high, an asymmetric equilibrium in which only one platform allows such behavior can emerge.

3 - Optimal Resource Allocation Strategies for Venture Capitals in a Contest

Manman Wang, University of Science and Technology of China, Hefei, China, People's Republic of, Zihao Zhang

Many innovators compete with each other to meet the refined needs of consumers. Should venture capitals (VCs) favor a high-efficiency or low-efficiency start-up in a contest? Despite a widespread emphasis on investing more capital in the best start-up, a VC continues to invest in poor performers. We simulate the investment decisions of monopoly VC and competing VCs in competing start-ups through contest theory. We find that a monopoly VC will always invest more in inefficient start-ups and artificially reduce the success rate of efficient start-ups, thus prompting both start-ups to expend more effort. As for competing VCs, the VC with strong funds will take the initiative to invest more in inefficient start-ups under certain conditions. Our study provides some new insights for VCs on how to effectively allocate resources in highly competitive startups.

4 - Integrating LLMs and Psychometrics: Global Construct Validity

Sen Yan, University of Colorado, Boulder, Boulder, CO, United States, Kai Larsen, Roman Lukyanenko

The psychometric approach in IS offers a foundational framework for a broad spectrum of research endeavors, which typically rely on construct validation to confirm that a series of indicators accurately measures the intended construct. However, a longstanding issue with construct validity, unaddressed since its introduction by Cronbach and Meehl in 1955, is that it is evaluated using study-specific response data without comparison to constructs outside the study. This oversight (or, rather, incapability) has significant implications. We introduce a large language model combined with principal components analysis (PCA) and develop the Validity Lodestar application. This approach lays the groundwork for developing more accurate and reliable theoretical models, marking a significant leap forward in the IS discipline's methodological capabilities, making IS the first of more than a dozen psychometric disciplines with the capability to evaluate construct validity truly.

AI-Driven Insights: From Operations to Financial Decision Making

Contributed Session

Chair: Hao Huang, Yuan Ze University, 135 Yuan-Tung Road, Chung-Li, Taoyuan, 32003, Taiwan

1 - Decision-Aware Predictive Model Selection for Individualized Worker Assignment

Eric Stratman, University of Wisconsin, Madison, WI, United States, Laura Albert, Justin Boutilier

Organizations depend on human decision-makers, especially in high-risk industries where information is scarce. Recognizing that a workers' experience influence their decisions, we propose a framework that integrates machine learning with integer optimization to assign tasks based on behavioral insights. Our method is a decision-aware approach that optimizes predictive model selection and data aggregation of the machine learning task for each worker to best support the downstream assignment task. We show this approach is crucial in environments characterized by complex predictions and limited data. We apply our proposed method to assign a workforce of insurance underwriter to requests for auto insurance, showcasing significant improvements in operational efficiency.

2 - Integrating Human Knowledge through Action Masking in Reinforcement Learning for Operations Management: A Case Study Analysis

Mirko Stappert, University of Freiburg, Freiburg im Breisgau, Germany, Bernhard Lutz, Niklas Goby, Dirk Neumann

Reinforcement learning (RL) provides a powerful method to address problems from operations management. However, its real-world application often fails due to a lack of user acceptance and trust. In particular, managers should be provided with possibilities of altering the learned policy by including human expert knowledge. In this study, we analyze the benefits and limitations of including human knowledge via action masking. While action masking has been used to exclude invalid actions, its potential to incorporate human knowledge and enforce specific actions has not been explored yet. We present the results of three numerical case studies focusing on the problems of peak load management, paint shop scheduling, and inventory management. Our findings suggest that using action masking to include human knowledge in the form of reasonable heuristics can lead to considerable cost reductions. Furthermore, we find that including human knowledge can be strictly necessary to learn effective policies for problems with a constrained action space, where certain actions can only be performed a limited number of times. At the same time, action masking should also be used with care since enforcing overly strict heuristics can prevent the RL agent from learning optimal policies. Our study contributes to the operations management literature by outlining ways of incorporating human knowledge into machine learning methods, which also provides valuable guidance for managers opting to employ RL in real-world applications.

3 - Empowering Financial Decisions: Unveiling LLMs' Potential in Sentiment Analysis

Sorouralsadat Fatemi, University of Illinois at Chicago, Chicago, IL, United States, Yuheng Hu

Financial sentiment analysis is vital for informed decision-making in finance, leveraging Large Language Models (LLMs) for effective insights. While LLMs excel in various NLP tasks, their full potential in financial sentiment analysis remains untapped. We explore two strategies: in-context learning (GPT-3.5, GPT-4) and fine-tuning LLMs on finance data, focusing on smaller models (250M to 7B parameters) due to computational costs. Comparing with state-of-the-art results, we find that fine-tuned smaller LLMs match or surpass larger counterparts, even with less data. Zero-shot and one-shot performance also align well with fine-tuned models and benchmarks. Interestingly, increasing in-context learning shots doesn't significantly boost sentiment analysis performance in finance. This research highlights the promise of appropriately tailored LLMs for robust financial sentiment analysis, aiding decision-makers amidst market fluctuations.

4 - Developing a Machine Learning-Based Warning System for Predicting Graduation as Scheduled Based on University Student Course Performance

Hao Huang, Yuan Ze University, Taoyuan, Taiwan, Stevanus Calvin Widianto, Ray F. Lin

This study introduces an approach to constructing a warning system tailored to forecast students' likelihood of graduating as scheduled, predicated on their course performance. We implement random forest and artificial neural network algorithms as our prediction model. Through melding these advanced machine learning techniques with comprehensive academic data increases each semester, multiple models are created for different time periods of a student's progression. For instance, there is a model for predicting student's graduating as scheduled after the first semester, whereas another model is trained for the same prediction after the second semester with more course performance data. Overall, eight models are trained for the four-year period of a student's university progression. The numerical experiment is currently implemented with the students from the Department of Industrial Engineering to illustrate the potential of the warning system. This warning system endeavors to furnish timely interventions for students deemed at risk of academic setbacks, thereby potentially fortifying retention rates and nurturing scholastic achievement. In summation, this study engenders discourse on the potential of machine learning in education.

By forging a robust warning system, universities could be poised to identify and support students encountering academic hurdles, fostering a conducive environment for student success.

Advanced Decision-Making and Optimization Techniques

Contributed Session

Chair: Yuan Dong, Temple University, philadelphia, PA, United States

1 - The Economic Impact of Environmental Product Declarations and Low-Carbon Certifications: A Case Analysis of South Korean Companies

Jeongmin Shin, Kyung Hee University, Yongin, Korea, Republic of, Jungwoo Shin

This study analyzes the performance of environmental performance declarations (EPDs) and low-carbon certification schemes to investigate whether labelling environmental performance alone can lead to significant results. The analysis of the performance of companies according to their certifications was conducted in Korea. We used a database containing information on 57,908 Korean companies and a list of 822 EPD certified companies and 282 low-carbon product certified companies published on the Environmental Technology Business One-Stop Service. To compensate for the lack of small and medium-sized enterprises (SMEs) data in the collected Korean company database, an additional company survey was conducted to build the final analysis database. The propensity score matching (PSM) methodology was used to compare certified and non-certified companies, and selection bias was adjusted to obtain direct results. The results showed that companies with Ecolabelling and low-carbon certification experienced a significant increase in sales between one and two years after certification. This suggests that environmental certification can contribute to improving corporate performance and increasing competitiveness in the marketplace.

2 - Improving Support Vector Ordinal Regression for Enhanced Performance in Outlier and Imbalanced Datasets

Stephan Jao, Department of Information Management, National Chi Nan University, Nantou, Taiwan, Puli, Taiwan, Jing-Rung Yu, Chun-Yen Tsai, Donald Lien, Hung Pi-Hsia, Chi-Chun Chien

Support Vector Ordinal Regression (SVOR) is a classification method that classifies multiple classes with preference orders. Given a dataset with r ranks, the SVOR obtains r-1 parallel hyperplanes (classifiers) with r-1 thresholds in order to categorize the training data with the hinge loss function by maximizing the margins between ranks. Outliers and imbalanced data appear frequently in real-world datasets. The appearance of outliers in a dataset affects the magnitude of the classification error and hence influences the position of the hyperplanes, especially narrowing the range of ranks situated between hyperplanes, and resulting in lower classification accuracy. Furthermore, SVOR is weak at handling imbalanced data, especially when the classification outcome is affected by the majority class. Research shows resampling methods to address imbalance problems tend to suffer from information loss, overfitting, and increased model complexity. Meanwhile, cost sensitive learning maintains the completeness of the dataset. This study proposes an l_1-norm SVOR model with bounded loss functions. The training results are surveyed to evaluate the impact on outliers. In addition, we will also adjust the loss function by adding a higher penalty to the misclassification error in each corresponding rank. The proposed method is applied to an imbalanced dataset, which is composed of financial data of Taiwanese companies from 2009 to 2022 to predict financial distress. The data is composed of 3 ranks, with rank 1 being the majority rank. Comparisons highlight advantages of our study in classification accuracy and cost-effectiveness for dealing with outliers and imbalanced datasets.

3 - On the Approximability of the Yolk in the Spatial Model of Voting

Ran Hu, Rensselaer Polytechnic Institute, Troy, NY, United States, James Bailey

In the spatial model of voting, the yolk and LP (linear programming) yolk are important solution concepts for predicting outcomes for a committee of voters. McKelvey and Tovey showed that the LP yolk provides a lower bound approximation for the size of the yolk and there has been considerable debate on whether the LP yolk is a good approximation of the yolk. In this paper, we show that for an odd number of voters in a two-dimensional space that the yolk radius is at most twice the size of the LP yolk radius. However, we also show that (1) even in this setting, the LP yolk center can be arbitrarily far away from the yolk center (relative to the radius of the yolk) and (2) for all other settings (an even number of voters or in dimension $k \geq 3$) that the LP yolk can be arbitrarily small relative to the yolk. Thus, in general, the LP yolk can be an arbitrarily poor approximation of the yolk.

4 - The Impact of Investor Irrationality on Firm Value and Market Efficiency

Wei HU, School of Economics and Management, Tongji University, Shanghai, China, People's Republic of, Xiurui YANG

The short squeeze event involving GameStop (Ticker: GME) in 2021 was a landmark event that underscores the transformative power of market irrationality in shaping the financial markets. Retail investors launched a campaign through online forums and social media platforms to counter short-selling institutional investors by purchasing GameStop stock. Using a dataset from *Stocktwits*, a professional social media platform for stock discussions, we examine the causal effects of the GME short squeeze on the firm value and market efficiency for 367 SP500 listed stocks from October 2020 to April 2021. Firm value is assessed using abnormal returns, while market efficiency is proxied by the social media users' forecast accuracy (SMUFA). We utilized pre-trained language models to predict the sentiment of messages and employed graph embedding models to identify GME-related stocks. A difference-in-differences approach combined with propensity score matching reveals that GME-relevant stocks exhibited a significant decline in both abnormal return and SMUFA compared to GME-irrelevant stocks after the short squeeze. These findings suggest that market irrationality negatively impacts firm value and market efficiency. Our results, which successfully passed a series of tests and proved robust, offer significant theoretical contributions and practical implications.

5 - Media Optimization with Nbcuniversal One Platform Total Measurements

Hanxi Bao, NBCUniversal Media, LLC, New York, NY, United States

NBCUniversal launched One Platform Total Audience (OPTA) at beginning of 2024. The AI-driven planning and activation technology is the latest evolution within the company's One Platform offering and leverages new investments in automation and data to provide brands unduplicated reach through a single media buy across linear and streaming. OPTA allows advertisers to generate media plans across NBCU linear and digital media channels using more than 300 audience segments that connect audience attributes and outcomes. Together with OPTA, we established One Platform Total Measurement (OPTM) framework that delivers insights and outcome-based measurement across the entire funnel, from awareness to conversion. This presentation introduces the standardized measurement operating procedure and media planning optimization methods to find the optimal media mix at NBCUniversal to drive target outcomes.

6 - Product Pricing and Live Streaming E-commerce Frequency Decisions

Yuan Dong, Temple University, philadelphia, PA, United States, Guohou Shan, Subodha Kumar

Live streaming e-commerce (LSE) gradually becomes the future of shopping and creates hundreds of billions of markets. Influencers can demonstrate the product and interact with potential consumers in real-time on LSE platforms, reducing product uncertainty and raising the consumers' purchasing intention. In this research, we focus on understanding how online stores alter LSE frequency and pricing decisions to boost their revenue better. To better understand consumers' decisions, we also categorize consumers into product-oriented and influencer-oriented, aiming to understand the impact of consumer heterogeneity on store decisions. Our research makes both theoretical and practical contributions. On the one hand, we enrich the prior literature by focusing on exploring more nuanced decisions that a store can make regarding the LSE setting and adoption while considering customers' heterogeneity. On the other hand, our research findings can help online stores make better decisions and strategies as for leveraging LSE to boost their product sales and revenue.

Technology Showcase

1 - Topic Modeling or Taxonomy Building: Benefits, Drawbacks, and Implementation Strategies

Normand Peladeau, Provalis Research, Montreal, QC, Canada

Topic modeling is a "quick and dirty" heuristic method to inductively extract topics from large text collections. While it holds significant potential, the results can sometimes be suboptimal. This presentation will explore various strategies to enhance topic modeling outcomes, including alternative algorithms, the application of large language models (LLMs) and word embeddings, and automatic word sense disambiguation techniques. We will also identify limitations of topic modeling and how building text analytics taxonomies can serve as a more precise alternative for measurement, capturing low-signal events, and hypothesis testing. Although developing such taxonomies is time-consuming, we will demonstrate, using WordStat text analytics software, how various techniques and strategies can yield more accurate results more efficiently and how these two approaches can complement each other.

2 - Python and AMPL: Build Optimization Applications Quickly with amplpy, Pandas, Streamlit - and AI

Bob Fourer, AMPL Optimization Inc., Evanston, IL, United States

Python and its vast ecosystem are great for data pre-processing, solution analysis, and visualization, but Python's design as a general-purpose programming language makes it less than ideal for expressing typical complex optimization problems. AMPL is a declarative language that is designed for describing problems and that integrates naturally with Python.

In this presentation, we'll survey a range of contexts where AMPL and Python work together to make optimization software simpler to use, faster to run, and easier to integrate with enterprise systems:
- Installing AMPL and solvers as Python packages anywhere
- Importing and exporting data efficiently from/to Python data structures, including Pandas and Polars dataframes
- Modeling and solving in Jupyter notebooks on Google Colab
- Deploying to the cloud quickly and easily with Pandas, Streamlit, and amplpy

You'll also see how generative AI technology is enabling a rapid development process for both AMPL and Python, reducing the time and effort to produce working applications that are ready for end-users.

1 - Effects of Digital Commitment Contracts on Engagement in Underprivileged Children's Education: Evidence from a Field Experiment

Swanand Deodhar, Indian Institute of Management Ahmedabad (IIMA), Ahmedabad, India, Neaketa Chawla, Ambrish Dongre, Harsh Parekh, Yana Chello, Neetu Singh, Prashast Srivastava

Students' continued engagement in education programs, particularly among students from underprivileged backgrounds, has emerged as a pertinent problem in enabling the benefits of education. To this end, digital technologies may act as a mitigating force. Our study ascertains how digital interventions may increase engagement in a primary education initiative. Drawing from prior work on commitment theories, we argue that a digitally-enabled *Commitment Contract* (CC) may aid in improving target groups' engagement. We report findings from a randomized field experiment conducted through a non-government organization (NGO), which works to improve primary education in underprivileged communities located in North India. As a treatment, we sent WhatsApp notifications, seeking the recipients' commitment to undergoing an assessment of basic skills in *Mathematics* and *Hindi* (a prominent Indian language) within 48 hours of receiving the message. Our dataset comprises recipients' responses to the CC and the subsequent phone call for assessment by the NGO. Our estimates, based on randomization, matching, and a post-experiment survey, reveal that, on average, CC improves the efficiency of the evaluation system as fewer calls are required to complete the same levels of assessment. Moreover, we find that those who do not commit after receiving the CC prompt exhibit lower engagement than those in the control group, indicating that the CC may help in segmenting recipients based on their commitment. Lastly, based on the average cost of an assessment observed before the experiment, we show significant economic implications of CC for a resource-constrained organization such as an NGO.

2 - Exploring the Impact of Extended Reality Training Systems on Nursing Education: A Comprehensive Physiological Study

Kamelia Sepanloo, Purdue University, West Lafayette, IN, United States, Young-Jun Son, Janine Hinton

This presentation outlines the methodological framework and objectives of pilot studies aimed at assessing the effectiveness of mixed reality (MR) and virtual reality (VR) training systems in nursing education, with a particular focus on collecting and analyzing physiological measurements. The study seeks to explore how VR and MR technologies influence various physiological responses among nursing students during their training sessions. Key physiological indicators, such as heart rate variability and activity energy expenditure, are closely monitored to gauge engagement levels, stress responses, learning effectiveness, emotional reactions, fatigue, and workload.

The research follows a structured methodology, beginning with the design of immersive VR and MR scenarios tailored specifically to nursing education. This is followed by the careful selection of appropriate physiological sensors for data collection and the execution of controlled training sessions involving both students and faculty. A diverse range of training tasks and scenarios are incorporated to provoke a spectrum of physiological responses, facilitating a thorough analysis.

Furthermore, in addition to physiological data, feedback on usability and comfort is solicited from participants to inform iterative enhancements to the VR/MR training systems. This emphasis on user experience underscores the importance of integrating physiological measurements into the evaluation process to comprehensively assess the impact of VR and MR training systems on nursing education.

Ultimately, this holistic approach aims to lay the groundwork for future advancements in immersive learning experiences, potentially leading to a transformative shift in the landscape of nursing education through innovative technological modalities.

3 - Alteryx Location Analytics in Higher Education

Deanna Sanchez, Nova Geographica LLC, Denton, TX, United States

Alteryx is a global low-code platform that enables quick data analytics, including spatial and demographic analysis capabilities. Location analytics in Alteryx encompasses many features, and this presentation examines the spatial relationships between student and university locations. We will explore geocoding addresses, distance calculations utilizing drivetime analysis, and using Census block group demographics to efficiently perform outreach to specific student populations.

4 - Not All Doom and Gloom: ChatGPT, Knowledge Diversity, and Style Similarity in Online Communities

Chan Gyu Lee, Seoul National University, Seoul, Korea, Republic of, Jeongsik Lee, Hyunwoo Park

Understanding the dynamics of user behavior in online collaborative communities (OCCs) is essential to leverage and maximize the potential of these communities. While OCCs heavily depend on users' voluntary involvement, concerns have been raised regarding potential declines in user engagement following the introduction of ChatGPT, an advanced large language model. This study examines the disruptive impact of ChatGPT on user behavior within Stack Overflow—an OCC that is highly prominent and arguably most severely impacted by the technology shock—focusing on knowledge coverage and community cohesion. For the investigation, we use the entropy and linguistic-style match (LSM) methods to measure content diversity and linguistic style similarity, respectively, within the community. We then apply a difference-in-differences analysis to assess the causal effect of ChatGPT on these measures. Despite an overall decrease in the volume of user-generated posts following the introduction of ChatGPT, our empirical findings reveal a positive impact on knowledge coverage, indicating that ChatGPT helps enhance content diversity within the community. Additionally, the results indicate a trend of linguistic style homogenization, suggesting a more cohesive community environment potentially enabled by ChatGPT. Our study provides some early empirical evidence that, contrary to initial concerns about the introduction of ChatGPT threatening the role of OCCs, ChatGPT may have instead enriched and diversified community knowledge, fostering a more cohesive and collaborative environment for these communities.

Product and Process Innovation in Healthcare

Invited Session

New Product Development

Chair: Zhili Tian, Univ. of Houston, Houston, TX, United States

1 - Optimal Enrollment In New Drug Development With Learning of Drug' Efficacy for Clinical Trials

Zhili Tian, Univ. of Houston, Houston, TX, United States

The cost for developing a new drug ranged from $1 billion to more than $2 billion between 2010 and 2019. The efficacy of the candidate drug, patient enrollment, and the market exclusivity period (MEP) are uncertain. Moreover, slow enrollment leads to increased costs, canceled clinical trials, and lost potential revenue. Many firms hope to detect efficacy versus futility of the candidate drug early to save development costs in group-sequential-design trials. We developed a continuous-time dynamic programming model with learning of a drug's efficacy and MEP. We update a drug's efficacy by Bayes' rules and prove the value function and optimal properties using the stochastic order and the likelihood-ratio order of distribution functions. Our optimal policies can assist firms in developing optimal enrollment policies in their clinical trials. Firms can use the properties of the value function to select late-stage clinical trials for their drug-development project portfolios, use our optimal policy to guide patient recruitment in their clinical trials considering competition from other drugs in the marketplace, and use our model in simulation to select their trial design parameters.

2 - Digital Inclusion: Can Platform Affordances Mitigate Online Harassment?

Eujean Byun, University of California Merced, Merced, CA, United States, Lisa Yeo, Marie Yeh

Online harassment is defined as repeated malicious internet behaviors intended to upset or disturb victims, often conveying explicit or implicit threats. While anyone can be a victim, there is ample evidence that younger and marginalized people (i.e., vulnerable groups) experience online harassment more frequently and of greater severity; designing interventions is a critical tool in supporting justice, equity, diversity, and digital inclusion. This study examines strategies to reduce online harm by promoting bystander intervention; we further explore if personality traits play a role in moderating bystander intervention behaviors and their attitudes. Using the Truman Platform (simulated social media engine), we manipulate intervention design affordances of a social media platform and observe the impact on user intervention behaviors and their attitudes. We recruited participants via Prolific from February to April 2024, with 137 individuals completing the experiment. Participants were exposed to varying levels of harassment severity, reporting effort, dissent visibility, and rules reminders in $2\times3\times2\times2$ full factorial treatment groups and were randomly assigned to a treatment group. Participants completed a pre-experiment survey assessing select personality traits, engaged with our simulated social media platform over two days, and then completed a survey about their experience along with social behavior, and were debriefed about the deceptive nature of the platform. This study will inform better design to support and encourage bystanders to intervene, while also anticipating extending the work to address how to avoid the weaponization of these same systems to cause further harm to marginalized individuals and groups.

3 - Plastic Recycling Fueled with Blockchain-Driven Tokenization: ESG Optimization and Implications

Jim (Junmin) Shi, New Jersey Institute of Technology, Newark, NJ, United States, Aichih Chang, Nesreen El-Rayes, Fuqin Zhou

The plastic waste crisis has been witnessed to be exacerbating nowadays. To address the burgeoning challenge, one innovative solution is to incentivize recycling via leveraging tokenization thanks to Blockchain technology (BCT). In this study, we device an optimization model considering the tokenization to examine the environmental and social governance (ESG) performance. In particular, we investigate the optimal decisions of tokenization rewards and the government enforcement as well as their interplay on the ecosystem. We demonstrate the potential for significant ESG improvements by managing enforcement and tokenization jointly. Extensive numerical experiments and sensitivity analysis are performed to provide rich insights. For example, the value of tokenization in terms of ESG is visualized.

4 - Chinese EV Manufacturers: Integrating Industry 4.0 Technologies with Lean and Sustainable Manufacturing Practices to Elevate Operational and Innovation Performance, leading to sustainable production

Muhammad Adnan Zahid Chudhery, School of Management, University of Science and Technology of China, Hefei, China, China, People's Republic of, Sarah Safdar, Huafei Wei

In 2023, Chinese electric vehicle (EV) sales reached 9.49 million units. This included 2.80 million plug-in hybrids and 6.68 million pure battery-powered vehicles. Some Chinese EV manufacturers, such as BYD, are now competing with international players like Tesla to gain market dominance. Chinese auto manufacturers are currently facing the challenge of oversupply, leading to a fiercely competitive environment and a price war, resulting in reduced profitability. Experts predict that many smaller companies will not survive this situation. In this scenario, integrating Industry 4.0 with lean and sustainable manufacturing is crucial for these companies to achieve operational and innovative performance for sustainable production. Therefore, we conducted this study in Chinese EV manufacturing companies and collected data from knowledge employees and their direct managers. We argued that lean and sustainable manufacturing practices could help Chinese EV manufacturers elevate their operational and innovation performance, resulting in sustainable production using Industry 4.0 technologies. The study has significant theoretical implications for researchers and practical implications for government environmental authorities, policymakers, and EV manufacturing companies.

Novel Analytics and Machine Learning Approaches with Manufacturing Applications

Contributed Session

Chair: Thiraj Wegala, Auburn University

1 - Machine learning-assisted ultrasonic testing and its application in additive manufacturing

Thiraj Wegala, Auburn University, Auburn, AL, United States, Rongxuan Wang

Porosities are considered one of the most important defects in additive manufacturing as they directly influence the part's strength. The porosity level assessment is usually ex-situ and relies on expensive equipment such as XCT. Ultrasonic imaging has been used for internal metal defect detection but can only be resolved with millimeter-level accuracy, not enough for micrometer-level porosity detection in laser powder bed fusion. The main reason is the physics-driven model is only able to track strong and simple echoes from relatively large defects. In this work, a data-driven model is trained to demodulate weak and complex diffraction signals. When shooting a group of pulses with different phases and wavelengths into the part, some sound waves will be trapped or deflected by the porosities. Two ultrasonic microphones are used to collect those sound waves that being influenced by the porosities. They are mounted at different locations and angles to provide spatial information. The amplitude signal of the microphones is used as the input of the data-driven model, and the output is a porosity level map on the top surface of the part. With this information, remelting can be performed to release the porosities at the location that does not meet the requirements.

2 - Multiphysics-Informed Machine Learning using Sequential Learning for Surface Mount Technology

Abdelrahman Farrag, State University of New York At Binghamton, Binghamton, NY, United States, Jaewoo Kim, Daehan Won, Yu Jin

The electronics industry's continual drive towards miniaturization has posed unique challenges for Surface Mount Technology (SMT), especially in the assembly of printed circuit boards (PCBs). This paper introduces the ThermoDynaSMT framework to tackle the critical issue of predicting the final position of small-sized passive components, Self-alignment behavior, post the Soldering Reflow Process (SRP). The unpredictability of component placement arises due to a blend of factors including the surface tension of the solder paste, capillary effects, and the differential surface energy between the solder mask and copper pad. This behavior is modeled as a multi-physics problem considering the heat transfer principles governing the SRP and the mechanics influencing the movement of the components. ThermoDynaSMT integrates 2D Physics-Informed Neural Network (PINN) for predicting temperature distribution across the PCB, and a hybrid machine learning model for determining the final location of components with high precision. The ThermoDynaSMT framework combines real-time thermal profile adjustments with advanced predictive capabilities, achieving component placement precision within 10 micrometers. This precision is essential for maintaining the integrity and functionality of the assembled PCBs, ensuring adherence to Industry 4.0 standards. The model addresses limitations found in traditional methods, which typically rely on experimental data and trial-and-error adjustments, by employing sequential learning between its sub-networks to enhance stability and accuracy. Additionally, adaptive loss term weights are introduced to optimize the multiphysics modeling process in the PINN model, further improving the predictive control and enhancement of the manufacturing process in response to the evolving technological demands in the electronics assembly industry.

3 - A Mathematical Model to Optimize Capacity of a Complex Semiconductor Fabrication Plant

Jinyoun Lee, Samsung Electronics, Hwaseong-si, Korea, Republic of, Sungha Park, Seungho Lee, Euiseok Kum

In semiconductor FAB construction, substantial investment is required, making accurate assessment of FAB capacity crucial. This involves considering the complex nature of semiconductor FABs, including not only equipment perspective but also the analysis from a chamber-level perspective. Moreover, considering operational aspects such as complex product mix, priorities, and survival rates due to factors like destructive testing is crucial for accurate decision-making. This study proposes a mathematical model that considers chamber-level arrangement information and operational aspects of products, facilitating the derivation of optimal wafer production and capacity operation strategies. Additionally, it aids in identifying and analyzing bottleneck equipment or chambers during operations, thereby optimizing FAB capacity operation strategies in line with investments.

4 - Developing Integrative Production-Delivery System using Mobile Additive Manufacturing and Truck-Drone Delivery

Junfeng Ma, Mississippi State University, Mississippi State, MS, United States, Omid Abdolazimi

Recent advancements have seen the implementation of mobile additive manufacturing (MAM), which involves 3D printing technologies in moving vehicles, garnering considerable interest from both academic circles and industry sectors. Despite the potential benefits each technology offers to supply chain management, research integrating MAM with truck-drone delivery systems for daily operations is lacking. This study addresses this shortfall by combining these innovative technologies while also taking into account the preferred delivery time window of customers and the optimal sequence for printing. A mixed integer linear programming model is developed to facilitate this novel approach. To solve the model, both an exact method using CPLEX and a heuristic method via the Lagrangian relaxation algorithm are employed and evaluated. Computational experiments confirm the efficacy of the model and methods across small, medium, and large-scale problems, with the Lagrangian relaxation algorithm consistently outperforming in terms of optimality gap and CPU time. Furthermore, the model is applied in a real case study utilizing the Lagrangian approach. Findings reveal that the maximum drone flight range and the complexity of the printing tasks notably influence overall costs and meet customer delivery timelines. This system not only meets customer needs in a timely and cost-efficient manner but also enhances supply chain resilience, enabling businesses to boost service quality robustness and lessen reliance on inventory by producing spare parts on-demand through MAM technology.

5 - Different Batch Composition for Additive Manufacturing Machines in an Unrelated Parallel Machine Scheduling Problem

Fatemeh Pourdehghan, University of Missouri, Columbia, MO, United States, Ayhum Ishaq Asfour, Omid Shahvari, Sharan Srinivas

In the next decade, Additive Manufacturing (AM) will revolutionize component production with complex geometries, enabling on-demand creation at or near end- use locations. This shift reduces lead times and inventory, cuts transport distances, and enhances sustainability by lowering resource use and emissions. By using this technology, the manufacturer can quickly change for a revised version of the product which has less material waste during production. Where a degree of customization is required, particularly in additive manufacturing, considering an unrelated parallel machine layout is beneficial due to its structured production process to optimize efficiency. Our study focuses on batch processing in additive manufacturing on unrelated parallel machines, aiming to minimize total cost, including production cost, tardiness cost and rejection cost. To reflect real-world industry requirements, variable machine availability, dynamic job release times, different machine capability and eligibility, multiple raw materials, batch capacity constraints, sequence-dependent setup time, and customer prioritization are considered. Unlike many prior works, this study considers different batch compositions for machines. While the batch capacity depends on the raw material, the batch compositions depend on the required raw material, dimension, and volume of the jobs, as well as the necessary spacing between jobs in a batch. A mixed-integer linear programming model is proposed for small-size problems. Given the problem's NP-hard nature, we also introduce Simulated Annealing algorithm to tackle large size problems. The results demonstrate the algorithm's high level of effectiveness.

6 - A Hybrid Genetic Algorithm for Topology Optimization of Frame Structures for Additive Manufacturing

Oguz Toragay, Lawrence Technological University, Southfield, MI, United States, Nikan Mehrara, Daniel Silva, Alexander Vinel

In this ongoing research we consider the design of lightweight additively manufactured planar frame structures as a nonlinear, nonconvex optimization problem for which we propose a novel hybrid Genetic Algorithm (GA). Our motivation in proposing the metaheuristic is that the large-scale instances of frame structures cannot be tackled using existing exact methods from the literature. The proposed method is a hybrid GA, in that it consists of solving a nonlinear optimization problem to calculate the fitness values of the individuals in the population, in addition to other stochastic behaviors of classical GA. We also propose a novel encoding for the candidate solutions as the individuals in the GA's population, based on the paths that can be identified in the ground structure. Unlike traditional binary encoding, path-based encoding considers the mechanical behaviors of the structure and makes GA applicable in the discrete structure's topology optimization problem. Accordingly, we modified operators for the hybrid GA to handle the path-based encoding. Our numerical results showed that although the proposed hybrid GA is able to find the optimal solution for small-scale problems, the accuracy and consistency of the results suffer from the curse of dimensionality. We conclude that the proposed path-based encoding is a capable alternative for the traditional binary encoding that has been widely used for combinatorial optimization problems in the literature.

Topics in Integer Programming and Combinatorial Optimization 2

Invited Session

OPT: Integer and Discrete Optimization

Chair: Luze Xu, University of California, Davis, Davis, CA, 95616, United States

Co-Chair: Joseph Paat, University of British Columbia, Sauder School of Business, Vancouver, BC, Canada

1 - Breaking the quadratic gap for strongly polynomial solvers to combinatorial linear programs

Bento Natura, Georgia Institute of Technology, Atlanta, GA, United States

Recent years have seen tremendous progress in high-accuracy solvers for Maximum Flow, Minimum-Cost Flow and general Linear Programs (LP). Progress on strongly polynomial solvers for combinatorial LP on the other hand has stalled. For combinatorial LP beyond directed graphs this gap between exact and high-accuracy solvers is currently quadratic. We finally break the quadratic gap and design a strongly polynomial interior-point-method for combinatorial LP, which reduces the gap to only a linear factor.

2 - Fast algorithm design for structured linear programming

Sally Dong, MIT, Cambridge, MA, United States

An extremely fruitful line of algorithms research over the past decade has been the application of interior point methods alongside data structure design to classical problems in combinatorial optimization. In this talk, we consider linear programs of the form min <c,x> subjected to Ax = b, x >= 0, where the constraint matrix A has suitable structural properties. We present a general framework for solving these structured linear programs that ties together interior point methods and tools across theoretical computer science including graph decomposition, sampling, dynamic algorithms, and numerical linear algebra. Our framework in turn yields the fastest-known algorithms for min-cost flow and k-commodity flow on planar graphs, and for min-cost flow and general linear programs on graphs with bounded treewidth.

Based on joint work with Yu Gao, Gramoz Goranci, Yin Tat Lee, Lawrence Li, Richard Peng, Sushant Sachdeva, and Guanghao Ye.

3 - Sample Complexity of Algorithm Selection and its Applications to Branch-and-cut

Sammy Khalife, Johns Hopkins University, Baltimore, MD, United States

Can we learn efficiently good cutting planes to solve integer programs faster? What do we mean by efficient learning, and what is a good cutting plane? In this talk, I will delve into these questions, building upon recent work in data-driven algorithm design. This paradigm uses statistical and machine learning techniques to select from a class of algorithms for a computational problem an algorithm that has the best expected performance with respect to some (unknown) distribution on the instances of the problem. In this context, instead of selecting a single algorithm that has the best performance, we allow the possibility of selecting an algorithm based on the instance to be solved. In particular, given a representative sample of instances, we learn a neural network that maps an instance of the problem to the most appropriate algorithm for that instance. By formalizing this idea, I will present rigorous sample complexity bounds for this learning problem, in the spirit of recent work in data-driven algorithm design. We then apply this approach to the problem of making good decisions in the branch-and-cut framework for mixed-integer optimization (e.g., which cut to add?). In other words, the neural network will take as input a mixed-integer optimization instance and output a decision that will result in a small branch-and-cut tree for that instance. Our computational results provide evidence that our particular way of using neural networks for cut selection can make a significant impact in reducing branch-and-cut tree sizes, compared to previous data-driven approaches.

4 - Improving Strong-branching Decisions With Additional Information

Prachi Shah, ISyE, Georgia Institute of Technology, Atlanta, GA, United States, Santanu Dey

Strong-branching uses only the local gains in the linear programming (LP) bounds to guide the branching decision. In this work, we aim to refine it by incorporating information from primal bounds and the problem structure.

5 - Decomposition-Based Disjunctive Cutting Planes

Aleksandr Kazachkov, University of Florida, Gainesville, FL, United States, Ricardo Fukasawa

Many integer programs have either explicitly user-defined decomposition structure, such as in multistage stochastic integer programming, or naturally-occurring decompositions that can be automatically detected. Each part of the decomposition typically involves a small fraction of the larger problem, which allows for expensive computational techniques on the resulting subproblem that would be impractical for the entire problem. We investigate the generation of sparse disjunction-based cutting planes using the decomposition structure of instances.

Submodularity and Conic Optimization

Invited Session

OPT: Linear and Conic Optimization

Chair: Georgina Hall, INSEAD, Fontainebleau, France

1 - Distributionally Robust Optimization Through the Lens of Submodularity

Karthik Natarajan, Singapore University of Technology and Design, Singapore, Singapore, Arjun Ramachandra, Divya Padmanabhan

Distributionally robust optimization is used to solve decision making problems under adversarial uncertainty where the distribution of the uncertainty is itself ambiguous. In this paper, we identify a class of these instances that is solvable in polynomial time by viewing it through the lens of submodularity. This adds to the list of known polynomial time solvable instances of the multimarginal optimal transport problem and the generalized moment problem by bridging ideas from convexity in continuous optimization to submodularity in discrete optimization. In turn, we show that a class of distributionally robust optimization problems with discrete random variables is solvable in polynomial time.

2 - Sequential Competitive Facility Location: Exact and Approximate Algorithms

Ruiwei Jiang, University of Michigan, Ann Arbor, MI, United States, Mingyao Qi, Siqian Shen

We study a competitive facility location problem (CFLP), where two firms sequentially open new facilities within their budgets, in order to maximize their market shares of demand that follows a probabilistic choice model. This process is a Stackelberg game and admits a bilevel mixed-integer nonlinear program (MINLP) formulation. We derive an equivalent, single-level MINLP reformulation and exploit the problem structures to derive two valid inequalities based on submodularity and concave overestimation, respectively. We use the two valid inequalities in a branch-and-cut algorithm to find globally optimal solutions. Then, we propose an approximation algorithm to find good-quality solutions with a constant approximation guarantee.

3 - Sequential Submodular Maximization

Arash Asadpour, Zicklin School of Business, New York, NY, United States, Rad Niazadeh, Amin Saberi, Ali Shameli

We study a submodular maximization problem motivated by applications in online retail. A platform displays a list of products to a user in response to a search query. The user inspects the first k items in the list for a k chosen at random from a given distribution and decides whether to purchase an item from that set based on a choice model. The goal of the platform is to maximize the engagement of the shopper defined as the probability of purchase. This problem gives rise to a less-studied variation of submodular maximization, in which we are asked to choose an *ordering* of a set of elements to maximize a linear combination of different submodular functions. First, using a reduction to maximizing submodular functions over matroids, we give an optimal approximation for this problem. We then consider a variant in which the platform cares not only about user engagement, but also about diversification across various groups of users—that is, guaranteeing a certain probability of purchase in each group. We characterize the polytope of feasible solutions and give a bicriteria approximation for this problem by rounding an approximate solution of a linear-programming (LP) relaxation. For rounding, we rely on our reduction and the particular rounding techniques for matroid polytopes. For the special case of coverage functions—which is practically relevant in online retail—we propose an alternative LP relaxation and a simpler randomized rounding for the problem, yielding an optimal bicriteria approximation algorithm.

4 - Sum of Squares Submodularity

Georgina Hall, INSEAD, Fontainebleau, France

Submodularity is a key property of set-valued functions, appearing in many different areas such as game theory, machine learning, and optimization. In this talk, we consider set-valued functions with a multilinear extension of degree less than or equal to some k. For these functions, it is known that testing whether they are submodular is hard for k greater or equal to 4. We thus introduce a sufficient condition for submodularity based on sum of squares polynomials, which we refer to as sum of squares (sos) submodularity. We investigate the gap between submodularity and sos submodularity and show how to use semidefinite programming to optimize over this set. In particular, we use the techniques proposed to learn a submodular function from data, among other applications.

Co-Chair: Liwei Jiang, Georgia Institute of Technology, Atlanta, GA, United States

1 - On Reaching Local Minima of Nonconvex Nonsmooth Functions

Swati Padmanabhan, Massachusetts Institute of Technology, Cambridge, MA, United States

For Lipschitz functions, it is known that first-order algorithms converge to local minima asymptotically (due to a result by Davis, Druvyatskiy, and Jiang).
The natural next question then is whether these algorithms converge to local minima ``fast''. We prove a surprising negative result for this question. Specifically, we show that obtaining any non-trivial convergence rate in terms of local function decrease is impossible even for strict functions.
In particular, we prove that even under suitable regularity assumptions and the absence of non-strict saddles,
any algorithm whatsoever based on local queries cannot guarantee getting stuck at points at which there is significant local decrease,
unless the number of iterations grows exponentially with the dimension. In fact, this statement holds even under the supposedly easier case for which all approximate-stationary points below some constant (sub)gradient norm, are in fact global minima (which trivially precludes the existence of non-strict saddles).

This is based on joint work with Guy Kornowski and Ohad Shamir.

2 - Variational Theory and Algorithms for a Class of Asymptotically Approachable Nonconvex Problems

Ying Cui, University of California, Berkeley, Berkeley, CA, United States

In this talk, motivated by the inverse optimal value based non- linear optimization problems, we introduce a class of composite nonconvex functions, where the outer function is the sum of univariate extended-real-valued convex functions and the inner function is the limit of difference-of-convex functions. A notable feature of this class is that the inner function can be merely lower semicontinuous instead of continuously differentiable. It covers a range of important yet challenging applications, including the composite value functions of nonlinear programs and the value at risk constraints for continuous random vectors. We propose an asymptotic decomposition of the composite function that guarantees epi-convergence to the original function, leading to necessary optimality conditions for the corresponding minimization problem. The proposed decomposition also enables us to design a numerical algorithm to solve the composite minimization problem such that any accumulation point of the generated sequence, if exists, satisfies the newly introduced optimality conditions. Our derived results expand on the study of so-called amenable functions introduced by Poliquin and Rockafellar in 1992, which are compositions of convex functions with smooth maps, and the prox-linear methods for their minimization.

3 - A Superlinearly Convergent First-Order Method for Nonsmooth Optimization

Vasilis Charisopoulos, University of Chicago, Chicago, IL, United States, Damek Davis

Nonsmooth optimization problems appear throughout machine learning and signal processing. However, standard first-order methods for nonsmooth optimization can be slow for "poorly conditioned" problems. In this talk, I will present a locally accelerated first-order method that is less sensitive to conditioning and achieves superlinear (i.e., double-exponential) convergence near solutions for a broad family of problems. The algorithm is inspired by Newton's method for solving nonlinear equations.

4 - Linearly Convergent Algorithms for Nonsmooth Problems with Smooth Pieces

Jimmy Zhang, IE, Purdue University, West Lafayette, IN, United States, Sra Suvrit

Non-smoothness is a major bottleneck to efficient optimization. In the absence of smoothness, the theoretic convergence guarantee drops from linear to sublinear rates for convex programs, and becomes orders of magnitude worse for nonconvex programs. This huge gap is shown to be unimprovable for some worst-case non-smooth instances. Here we focus on some mild non-smoothness: the piecewise smooth (p.w.s) function whose domain can be partitioned into subsets such that the function restricted to each subset is smooth. The p.w.s function covers the relu function in neural network, the l1 penalty in sparse optimization, and the min-max saddle point problem in robust optimization as special cases. We present some **globally** linear convergent methods for optimizing the convex p.w.s smooth function satisfying the quadratic growth condition, and, as a corollary, we improve the iteration complexity for solving the weakly convex p.w.s problem by orders of magnitude. Importantly, our method does not require any knowledge about individual smooth pieces, thus it is applicable even to general non-smooth program exhibiting some local p.w.s structure.

Efficient Methods for Large-scale Optimization Using Inexactness II

Invited Session

OPT: Optimization Under Uncertainty

Chair: Robert Baraldi, Sandia National Laboratories, Seattle, WA, 87123, United States

Co-Chair: Johannes Milz, Georgia Institute of Technology, Atlanta, GA, United States

1 - Memory-Efficient Dynamic Optimization using Inexact Hessians and Randomized Sketching

Radoslav Vuchkov, Sandia National Laboratories, Albuquerque, NM, United States

Finding solutions to dynamic optimization problems can be hampered by the sheer amount of memory needed to store the state trajectory, which is crucial for evaluating both the objective function and its derivatives. Recently, a trust-region method proposed by [R. Muthukumar et al., SIAM Journal on Optimization 31(2), pp. 1242–1275 (2021)] addressed this issue by using randomized sketching to compress the state trajectory, leading to inexact gradient calculations. The method provided convergence guarantees thanks to its adaptive rank learning criteria. Our work builds upon that approach by incorporating secant Hessian approximations. However, the inherent randomness of sketching can render traditional secant update formulas ineffective in producing accurate Hessian approximations. This is because the difference between two gradients, calculated from distinct sketches, might lack consistency. To circumvent this, we introduce a sketched approximation of the

Hessian itself, eliminating the need for gradient difference calculations. The effectiveness of our approach is showcased through numerical experiments.

2 - Derivative-free stochastic optimization via regression-based objective function models

Johannes Milz, Georgia Institute of Technology, Atlanta, GA, United States, Anton Kleywegt, Siva Ramani

We develop algorithmic approaches for optimization problems in which only noisy function evaluations are available. Motivated by applications in which such evaluations are costly, our framework is specifically designed to use both previous and new evaluations. We construct local objective function models, using evaluations from carefully selected experimental design points around the current iterate. We develop model-based algorithms such as trust region methods and cubic regularization methods that put function evaluations to best use while taking the model error into account in step selection. Under mild assumptions, we establish the convergence of our algorithms. Numerical illustrations and comparisons are presented.

3 - Approximate Internal Models for Power System Control Design in Extreme Conditions

Sergio A. Dorado-Rojas, Georgia Institute of Technology, Atlanta, GA, United States, John Cortés-Romero, Daniel Molzahn

The internal model principle has been one of the most effective yet underlooked tools for synthesizing control systems. In essence, the principle states that if a model of the exogenous signal is embedded in the control algorithm, the main performance objectives, such as disturbance rejection and reference tracking, are attained. However, the requirement for an exact model might be too stringent in some applications, such as modern power systems. This talk will revisit the internal model principle and show application examples in power systems where approximate internal models emerge as promising solutions for satisfactory performance in adverse or extreme conditions.

Mitigating Distributional Ambiguity in Stochastic Programming

Invited Session

OPT: Optimization Under Uncertainty

Chair: Shixuan Zhang, Texas A&M University, College Station, TX, United States

1 - Value of Data for Distributionally Robust Optimization with Phi-Divergences

Jangho Park, Sungkyunkwan University, Suwon-si, Korea, Republic of, David Love, Guzin Bayraksan

In data-driven distributionally robust optimization, not all data has the same value on the optimal decision. This paper studies the value of additional data for distributionally robust optimization with phi-divergences. Additional data provides more information about the collected events. As a result, the relative information of the collected events increases compared to the uncollected events, resulting in a new optimization problem. We discuss whether the optimal value increases or decreases if one particular data is acquired and propose simple ways to estimate this value change before solving a new optimization problem. For situations where we do not know what value to be selected next, we discuss simple estimators for an average value change by considering all observed scenarios. This estimator helps to decide whether obtaining additional data is worthwhile or not before solving a new optimization problem. A necessary implication of this paper is that proposed estimators form the lower bounds of corresponding true values.

2 - Synthesizing Interactive Optimization and Expert Elicitation for Stochastic Programming Problems

John Nichols, Rensselaer Polytechnic Institute, Troy, NY, United States, Jennifer Pazour, Sandipan Mishra, John Mitchell

A way to better obtain informed estimates for input parameters required for stochastic programming problems is to combine interactive optimization and expert elicitation protocols. This research creates a framework that includes two connected optimization models that allow one to iteratively elicit a human expert for more information on stochastic input parameters. Preliminary results show that such an approach can reduce human elicitation efforts while achieving high design performance from the optimization model.

3 - Moment Relaxations for Wasserstein Distributionally Robust Optimization

Shixuan Zhang, Texas A&M University, College Station, TX, United States, Suhan Zhong

To mitigate in the distributional ambiguity in stochastic optimization problems, a popular approach is to consider a Wasserstein distance-based distributionally robust optimization (WDRO) counterpart. Beyond out-of-sample performance guarantee, such WDRO model allows adjustable in-sample conservatism that ensures the optimal decisions are asymptotically consistent. However, similar to robust optimization counterparts, WDRO often takes away convexity of the model and leaves an NP-hard problem associated with finding the worst-case expected value. Our work begins with the investigation of convex relaxations of these challenging WDRO problems where the objective function and constraints are polynomial. In this case, tight relaxations can be derived based on the moment information of the polynomials, and we show a simple condition that guarantees the same asymptotic order out-of-sample guarantee and in-sample adjustable conservatism as the original WDRO. This suggests that one may entirely use the moment relaxation as a surrogate for WDRO without asymptotic gaps. We provide numerical experiment results to illustrate these findings.

4 - Distributionally robust optimization-based infrastructure system maintenance planning

Zhengsong Lu, University of Pittsburgh, Pittsburgh, PA, United States, Bo Zeng

We develop a distributionally robust optimization model for the maintenance problem of an infrastructure system.

Optimization and Modeling in Industrial Applications

Contributed Session

Chair: Mojtaba Salarpour, Texas A&M University-Commerce, Commerce, TX, United States

1 - Optimizing Project Schedule and Cost for Construction of a Floating, Production, Storage, and Off-loading (FPSO) Unit

Lu Gao, University of Houston, Houston, TX, United States, Bruno Camargo

A floating, production, storage, and offloading (FPSO) is a floating vessel. The first was built in 1977 and used for the production and storage of hydrocarbon. Its use is cost-effective in particularly at deep water locations and requires low maintenance costs. Due to the volatility of the Oil&Gas markets, it has become increasingly important for organizations to develop innovative business strategies and cost-saving measures to counter the downturns of the industry. To answer this dilemma, FPSOs have emerged as an effective, efficient, and economical means to capitalize on oil fields around the world. FPSOs provide the same functionality as fixed platforms with the flexibility of relocating as needed in response to market conditions. In this project, we evaluated an FPSO erection project with the intent of identifying the optimal solution that will generate the shortest construction schedule and lowest possible project cost. Therefore, we developed an algorithm to detect the minimum cost, taking into consideration the fabrication (welding, NDT and Hydrotest) of piping streams, based on workers' salary, availability, and activities sequence. We also incorporated a daily bonus payment to incentive the fabrication company going ahead with the schedule. The results demonstrated that depending on the bonus value and workers' cost, the best-optimized solution will modify the activity sequence. On a large scale, this algorithm could be used to develop and solve real construction issues in the Oil&Gas industry, bringing direct revenue to the companies and improving the schedule with through an incentive bonus.

2 - Optimization of Prime Power and DRA Consumption in Refined Product Pipeline

Ling Zu, Colonial Pipeline, Alpharetta, GA, United States, Anthony Leo, Min Wang

In today's pipeline operations scenario, improving efficiency and lowering operational costs remains a top priority for industry stakeholders. This study investigates the optimization model to determine the optimal power utilization and drag reduction agent (DRA) usage in pipelines. Understanding how economic factors and operational performance interact, this study aims to clarify approaches that balance the need to save costs with the necessity of maintaining fluid integrity and continuous throughput. By leveraging mathematical modeling, optimization algorithms and cost-benefit analysis, it seeks to develop strategic solutions that balance economic considerations with operational efficiency. Through this interdisciplinary approach, the research aims to provide actionable insights that can inform decision-making processes and drive improvements in pipeline management practices.

3 - Equilibria in Interdependent Natural-Gas and Power Markets: An Analytical Approach

Amir Mousavian, Clarkson University, Potsdam, NY, United States, Beheshteh Raouf, Antonio Conejo

Natural-gas and power systems and their corresponding markets have evolved over time rather independently. However, both systems are increasingly interdependent since combined cycle gas turbines (that use natural gas to produce electricity) increasingly couple them together. Therefore, suitable analysis techniques are most needed to comprehend the consequences on market outcomes of an increasing level of integration of both systems. There is a vast literature on integrated natural-gas and power markets assuming that the two markets are operated centrally by a single operator. This assumption is often not true in the real world, which necessities developing models for these interdependent yet independent markets. In this vein, this paper addresses this gap in the literature and provides analytical Nash-Cournot equilibrium models to represent the joint operation of natural-gas and power markets with the assumption that the market participants in each market make their own decisions independently seeking maximum profits, as often is the case in the real world. We develop an analytical equilibrium model and apply the Karush-Kuhn-Tucker (KKT) approach to obtain Nash-Cournot equilibria for the interdependent natural-gas and power markets. We use a double-duopoly case to study the interaction of both markets and to derive insightful analytical results. Moreover, we derive closed-form analytical expressions for spot-market equilibria in both natural-gas and power markets, which are relevant and of practical significance for decision makers. We complement the duopoly-duopoly study with a detailed sensitivity analysis.

4 - Mastering Global and Local Variance in Mixed-Model Assemblies: Why the Variable Takt Outperforms the Fixed Takt

Philipp Pithan, WHU - Otto Beisheim School of Management, Vallendar, Germany, Arnd Huchzermeier

As demands on assembly lines rapidly increase due to product individualization, geopolitical risk hedging, sustainability requirements, and the introduction of new technologies, the fixed takt is severely challenged. To cope with variance in processing times across products and product variants, assembly line balancing typically deploys i) feeding lines, ii) floaters, iii) parallel stations, or iv) circular assembly for the efficient manufacturing on the same line. Product complexity is ultimately traded off against line inefficiencies.

We develop a general assembly line balancing model using the variable takt that optimally utilizes manufacturing resources and allocates work to them. Under very general assumptions, we show that a variable takt strictly outperforms the fixed takt with regard to line utilization and profitability when either i) a maximum takt or ii) a weighted-average takt time (WATT) is adopted. Furthermore, an increase in product individualization can be handled much more efficiently for the variable takt than for the fixed takt. When demand or mix uncertainty or seasonality increases, the fixed takt performs arbitrarily worse.

Assembly lines can be fitted to realize the shortest delivery lead time while achieving a more resource-efficient production of highly customized products, allowing for further profit growth. The choice of a fixed takt system not only constrains companies' customer centricity but also poses stress on the workforce. In a VUCA world, industries need to shift to a variable launching rate of products to eliminate process inefficiencies, worker stress, and constraints on product individualization, respectively (technology) innovation.

5 - Global Competition in Semiconductor Manufacturing: A Two-Stage Stochastic Supply Chain Network Model Approach

Mojtaba Salarpour, Texas A&M University-Commerce, Commerce, TX, United States, Kian Zeinolabedinzadeh

Semiconductors are essential to modern technology and nowadays they are widely used in many different fields, including computing, communications, medical technologies, and defense capabilities. The recent disruptions in the semiconductor supply chains, exacerbated by the COVID-19 pandemic, have exposed significant vulnerabilities in their global supply chain and have intensified the competition for leadership in semiconductor production globally so that the world's major powers consider it as one of their most important strategic priorities. In this study, we focus on the increasing global competition in semiconductor manufacturing by introducing a mathematical model wherein each country faces a two-stage stochastic optimization model to enhance its semiconductor manufacturing capabilities. In the first stage, countries prepare for a potential global event by boosting production capacities; in the second stage, they manage procurement strategies considering the event's impact on global supply chains and resource availability. Using the concept of variational inequalities, we develop an algorithm to solve several numerical examples that include various scenarios and strategies. Through our analysis of these examples, we provide insights into how different factors and decisions influence the outcomes of global competition in semiconductor manufacturing.

1 - Exact Solution Method for Multi-Stakeholder Freight Transportation Systems under Uncertain Demand

Mojtaba Hosseini, University of Iowa, Iowa City, IA, United States, Gita Taherkhani, Ali Hassanzadeh

This study focuses on investigating the tactical planning of an integrated multi-stakeholder system. The system receives time-dependent requests from carriers and shippers and optimizes in time and space the operations and transportation activities through the consolidation of loads of different shippers into the same vehicles. The demand values of shippers are taken under uncertainty. The aim of tactical planning in this system is to build an efficient service network and schedule. to satisfy the demand and requirements of shippers by making use of the predicted services and their capacities offered by the carriers. A two-stage stochastic program is presented and an exact decomposition-based algorithm is developed. Extensive computational analysis is performed to evaluate the impact of uncertainty on the solution of the proposed model.

2 - Effects of route-related safety risk factors on the optimal location of delivery hubs for an urban logistics network

Jihun Kang, Inha University, Incheon, Korea, Republic of, Junsu Kim, Jonghoo Lee, Hosang Jung

The acceleration of urbanization and the continuous development of e-commerce have concentrated population and logistics demands in urban areas, thereby increasing the complexity of urban logistics networks. This rise in complexity has heightened safety risks, exacerbated by logistics facilities and freight trucks, which negatively affect nearby residents and commuting traffic. In response, this study proposes a p-median based optimization model to address the delivery hub location problem, incorporating economic considerations and six safety risk factors for each route. These six factors, identified through a review of relevant literature, are traffic congestion, road accessibility, safety zones, driver's visibility, left turns at intersections, and density of junctions. The objective is to select a delivery hub that minimizes the weighted sum of distances and safety risk scores, calculated using these factors. Using real data from the Korea postal network and demand locations (post offices) in Seoul, we assign travel distances and safety risk scores between candidate delivery hubs in the Seoul Metropolitan Area. A sensitivity analysis is conducted to explore how varying the weights of economic costs and safety risk scores affects the optimal location. Our findings underscore the significant impact of safety risk factors on delivery hub selection and delineate optimal trade-offs between economic and safety considerations.

3 - Sensor-Driven Predictive Vehicle Maintenance and Routing Problem with Time Windows

Iman Kazemian, Wayne state university, Detroit, MI, United States, Murat Yildirim, Bahar Cavdar

Advancements in sensor technology have revolutionized how we manage the maintenance of vehicle fleets by providing better predictions of vehicle-specific failures. This change shows a big shift in how we predict failures, highlighting the important role of sensor data in addressing risks during operations. However, it is often challenging to transition from vehicle-specific predictions to practical applications in operations and routing. This paper addresses this problem by formulating an optimization problem in the presence of complex operational interactions. A new framework has been developed, integrating sensor-driven vehicle prognostics with a single-vehicle routing problem with time windows. To quantify the impact of failure risks predicted by sensor data, we use an adaptive maintenance cost function that changes dynamically as a function of remaining useful life (RUL) distributions. This approach helps to balance early maintenance, which can waste the remaining useful life, and delayed maintenance, which increases the risk of failure. Routing problems with time windows are inherently challenging, and integrating maintenance considerations adds significantly to its computational complexity. To address this, we have developed the 'Iterative Alignment Method' a new heuristic that builds upon the iterative solution techniques of the Lin-Kernighan-Helsgaun (LKH) algorithm. This approach generates high-quality solutions and enables the handling of large-scale problems efficiently. Moreover, compared to the traditional periodic maintenance strategy, our method shows improvements in operational and maintenance costs as well as in overall fleet reliability.

Advancements in Ride-Sharing System Optimization

Contributed Session

Chair: Shenyang Chen

1 - Non-myopic Dispatch in On-Demand Ride-Pooling Systems Using Reinforcement Learning

Farnoosh Namdarpour, New York University, Brooklyn, NY, United States, Joseph Chow

Ride-pooling, also known as ridesharing, shared ride-hailing, or microtransit, is a service wherein passengers share rides. Passengers are typically assigned to vehicles through a centralized fleet dispatch algorithm, allowing for pickups and drop-offs along the route. This service can reduce costs for both passengers and operators and reduce congestion and environmental impacts. However, a common limitation of such services is their myopic decision-making approach, ignoring the long-term consequences of dispatch decisions made at any given point. One promising solution to address this challenge is the application of reinforcement learning (RL). While RL has been extensively studied in the context of ride-hailing systems, there is a scarcity of literature exploring its use in ride-pooling systems. In this study, we build upon the learning and planning framework proposed by Xu et al. for ride-hailing systems, extending it to enable non-myopic decision-making in ride-pooling systems. By employing n-step temporal difference learning, we derive spatiotemporal state values, and subsequently evaluate the effectiveness of the non-myopic policy using NYC taxi data. Results demonstrate that the non-myopic policy leads to significantly lower rejection rates and shorter travel time for passengers at the cost of slightly longer traveled distances by vehicles compared to the myopic policy. Furthermore, in addition to enhancing performance metrics, the implementation of the non-myopic policy can substantially decrease fleet size, thereby offering significant cost savings for operators.

2 - Real-Time Large-Scale Ridesharing with Flexible Meeting Points

Zuhayer Mahtab, University of Southern California, Los Angeles, CA, United States, Maged Dessouky

Rideshare systems can increase the efficiency of the transportation system in large metropolitan areas of the United States. It increases efficiency by providing flexible and convenient commutes to passengers, thereby reducing the number of solo drivers. For a real-time rideshare system to be effective, drivers and passengers need to be matched quickly with minimal waiting time. Also, drivers need to be provided with routes that will minimize their detours and the total traveling cost of the system. This matching and routing system needs to be scalable to implement a rideshare system on a city-wide scale.

Dynamic ridesharing system performance can be improved by forecasting future demands from historical data. Also, the rideshare routes provided to drivers may need to be updated in real time as traffic conditions change. In this project, we develop a framework that, in real-time, matches drivers to passengers and route rideshare drivers that incorporates traffic data and future demands to provide improved routes. Our solution framework uses traffic simulation software to achieve this goal. We also incorporate common pickup and drop-off points for multiple passengers, potentially reducing travel costs and time. Additionally, we include an incentive system that will reduce passengers' traveling costs, promoting the adoption of rideshare systems. Our proposed framework is scalable to large metropolitan areas' demands.

3 - Achieving Balanced Pickup Waiting and Detour Delay: An Analytical Model for Ride-Sharing Based on Dynamic Bipartite Matching

Shenyang Chen, University of California-Davis, Davis, CA, United States, Michael Zhang

Spontaneous ride-sharing services have more room for improvement as they compensate for the insufficient supply of e-hailing taxis. The origin-matching strategy, commonly used by e-hailing taxis to minimize pickup waiting time, can lead to considerable detour delay if directly applied to ride-sharing services. Improving the service quality of ride-sharing systems requires balancing pickup waiting time, detour delay, and vehicle mileage savings. This study developed an analytical model to investigate the effectiveness of an ellipsoid matching strategy in balancing riders' pickup waiting time and detour delay. Based on the dynamic bipartite matching algorithm, this strategy incorporates riders' origins and destinations into the matching cost calculation, thereby reducing detour distances.

Regarding the competition among idle vehicles and pool-seeking vehicles, we compare the performance measures of simultaneous matching and sequential matching (i.e., riders are matched to pool-seeking vehicles first and then to idle vehicles). By deriving closed-form formulas of matching probability and expected travel distance, we provide a reasonable estimation to evaluate the impact of demand and supply on the rider's average service time, including pickup waiting time and onboard travel time. The numerical experiments demonstrate that the ellipsoid matching strategies offer practical benefits, showing a significant reduction in detour delay and a minor increase in pickup waiting compared to the origin-matching strategy. Specifically for ellipsoid matching, we find that simultaneous matching outperforms sequential matching in terms of vehicle mileage savings.

Surface and Airport Operations

Contributed Session

Aviation Applications

Chair: Mohammad Reihaneh, IESEG School of Management, La Garenne Colombes, France

1 - Dynamic Departure Pushback Control at Airports: Hybrid Models, Simulations, and Policies

Jita Desai, IIM-Bangalore, Bangalore, India, Sandeep Srivathsan, Guan Lian

Airport surface congestion can lead to significantly long taxi-out times, increased fuel-burn costs, and excessive emissions of greenhouse gases. To curtail these undesirable effects, we propose multiple hybrid penalty-based dynamic pushback control (HPDPC) policies that employ penalty functions dependent on both the taxiway queue limit and the current queue length to ration the pushback frequency at airports, and trades taxiway queueing times with gate-hold delays to minimize the total operational cost (fuel-burn and gate-hold costs). Using data from Beijing Capital International (PEK) airport, the performance of the proposed policies are compared with that of the no-control (baseline) policy, the traditional K-control policy, and the recently proposed penalty-based dynamic pushback control policy. Detailed Monte Carlo simulations and analytical models that study the sensitivity of the total cost function to various problem parameters are presented, and our results indicate that deploying a HPDPC policy that is more stringent than the K-control policy but more flexible than the PDPC policy can be beneficial. Additionally, we also show that deploying a very stringent policy can be detrimental to overall system performance, thereby validating the practical efficacy of the proposed HPDPC policies.

2 - Optimizing Aircraft Taxi Processes: A Multi-Server Queueing Model with Cost-Minimizing Queue Discipline

Kevin James, Brigham Young University, Provo, UT, United States, David Grimsman

Optimization of the aircraft taxi process can significantly decrease operating costs for air carriers, especially at major airports where taxi processes are multi-phased. To improve the efficiency of this process, we model the problem as a queueing system with numerous servers, to allow for cases where multiple runways act as servers in parallel. Additionally, we propose a novel queue discipline which minimizes the mean cost of delays over all flights at a given airport. As an alternative to FIFO, the proposed discipline accounts for aircraft delays at the gate before the aircraft enters the queueing system. We give a sensitivity analysis of the optimized output of our model to perturbations in the variance of service times and arrival rates. Finally, we demonstrate our results via simulation of an example system operating under normal conditions.

3 - Intelligent Routing of Baggage Handling System via Shortest Path-Guided Reinforcement Learning

Keyu TIAN, City University of Hong Kong, Hong Kong, Hong Kong, Li Zeng

Real-time routing of baggage handling system (BHS) becomes challenging with the rising of air travel demands and the advancements of conveyor systems. Traditional methods for solving the shortest path (SP) problem have been used for routing planning. Recently, reinforcement learning (RL) was introduced to this field due to its intelligence in dynamic decision making. However, the vast sample space required for the RL model and the lengthy training time resulted pose an obstacle to implementing this method in practice. This study proposes a novel method called the shortest path-guided reinforcement learning (SP-guided RL) to solve this problem. We adopt a double deep Q-network for RL and use shortest path strategy to direct the training of RL to reduce the exploration sample space and save training time. Furthermore, to enhance the robustness of the model to variations in baggage handling practice, we expand the conventional framework of routing planning to include two critical aspects, including the optimal arrangement of airlines in the BHS and data generation based on limited observations using the Wasserstein conditional generative adversarial network (WCGAN). Simulation study and case study validate the superior performance of the proposed method over existing methods and provide insights about the effect of SP guidance in optimal routing.

4 - Improving Efficiency of Aircraft Turnaround Time in Airport Ground Operation

Jamorn Wacharasing, Chulalongkorn University, Bangkok, Thailand, Natchaphol Prakobphol, Ponlapat Phataraphruk, Pitaakphong Rattanagraikanakorn

This research addresses the need for efficient Turnaround Time (TAT) management in aviation by modifying the ground handling process, providing actionable insights for enhancing the competitiveness and sustainability of the aviation sector. The systematic approaches involve data collection, solutions design, empirical modeling for performance analysis, and optimization analysis. The significance has been made in reducing TAT, particularly in unloading and loading operations which are highlighted as the most-time consuming tasks. The data collection is made with the observation of 39 samples in two airports including Suvarnabhumi Airport (Bangkok, Thailand) and Changi Airport (Singapore). The proposed solutions offer practical strategies for minimizing operational time of both processes. The empirical models are developed to be used in conducting the performance analysis to ensure the ability of each solution in reducing the operational time. Apart from the performance, the financial and environmental impacts are also considered in optimization analysis. The research found that the optimal solutions are 1. Additional Prepared Dollies for Unloading Process and 2. Containers and Pallets Ordering for Loading Process together can minimize the TAT by 5 minutes per flight which considered as the reduction of carbon emission by 222 tons per year, and it also provide cost saving of 15.79 million US dollars per year with the additional revenue generation of 33.01 million US dollars per year for the airlines by scheduling 565 additional flights. However, challenges which are operational variations and sample size limitation warrant further research.

5 - A branch-cut-and-price algorithm for the aircraft sequencing problem with aircraft holding options

Mohammad Reihaneh, IESEG School of Management, Paris, France, Hamed Reihaneh

Efficient utilization of runways, as major bottlenecks at airports, not only minimizes flight delays but also plays a vital role in reducing fuel emissions and mitigating environmental impacts. Aircraft sequencing problem (ASP) studied in this paper seeks to improve this efficiency through optimally sequencing departure/arrival aircraft on multiple runways. Most of the literature on ASP assumes that arriving aircraft can land at any time in a given time windows through speed adjustment. However, in this paper we study a more realistic variant of ASP where arrival flights can adjust their landing time through either "speed adjustment" or "airborne holding". This ASP problem is formulated as a set-partitioning model and solved using a branch-cut-and-price (BCP) algorithm. The proposed algorithm is also compared against the state-of-the-art algorithm for the base ASP (without holding patterns). Computational results show that the new algorithm is in several orders of magnitude faster and capable of solving larger instances within the given time limit.

Green House Gas Reduction in the North American Railway Industry

Invited Session

Railway Applications

Chair: Xuesong (Simon) Zhou, ASU, 11235 E Beryl Ave, Tempe, AZ, 85259, United States

Co-Chair: Tyler Dick, University of Texas at Austin, Austin, TX, United States

1 - Quantitative Evaluation and Optimization of the Potential Benefits of Battery Electric Locomotives with ALTRIOS

Diwen Shi, University of Texas at Austin, Austin, TX, United States

In an effort to decarbonize, North American freight railroads are exploring alternative energy technologies such as the Battery Electric Locomotive (BEL). A BEL produces tractive effort from electricity stored in onboard batteries that are re-charged at terminal stations and/or through regenerative braking. Because of their dependance on braking energy, the performance, range, and diesel fuel savings of BELs are expected to be highly variable between particular routes, train types and operating plans. To investigate these potential sensitivities, the diesel fuel savings obtained by adding BELs to conventional diesel-electric locomotive consists is simulated with the Advanced Locomotive Technology and Rail Infrastructure Optimization System (ALTRIOS). Using validated mathematical formulas developed by the research team to describe freight train, conventional locomotive, and BEL performance, ALTRIOS simulations provide detailed energy profiles across a range of BEL deployment scenarios. Analysis of terminal charging strategies and charger power rates reveals a trade-off between battery size, charge rate and annual energy savings. While general trends are observed, BEL implementations must carefully match battery capacity and charging strategy to operational needs on a case-by-case basis, instead of standardizing across all routes. This observation leads to a challenging optimization problem of efficiently deploying different size BELs to specific train runs and topography. Overall, BELs show promising model results in terms of reducing the diesel fuel consumption and emissions of mainline freight railroad operations. The various mainline deployment strategies investigated here demonstrate the potential versatility in BEL application by freight railroad practitioners outside of limited yard and terminal service.

2 - IMAGINED: Inter Modal Analytics for Green Infrastructure Network Energy Decarbonization

Hani Mahmassani, Northwestern University, Evanston, IL, United States, Pablo Durango-Cohen, Adrian Hernandez, Craig Philip, Hiba Baroud

We describe the development of an online, open-source platform to support the (re)design and operation of the nation’s multimodal freight transportation and logistics system. The objectives are to inform/optimize the transition from existing fossil fuels to alternative/renewable energy sources, and to improve the resilience freight transportation systems to disruptions. The platform consists of interrelated modules to support evaluation, selection, and roll out of infrastructure investments across the nation’s multimodal freight network encompassing roadways, railways, and waterways, including the facilities and vehicles that connect them and ensure their safe and efficient operations. Because transloading terminals play crucial roles in determining the feasibility and efficiency of intermodal operations, and are thus essential nodes in decarbonizing the entire system, the platform includes a microsimulation module focusing on these hubs. In addition, the platform includes modules of interest to shippers and carriers to support freight routing on intermodal corridors, and to support the renewal of vehicle fleets.

3 - Intermodal routing on road and rail with comparisons of green-house gas emissions

Marc Meketon, Oliver Wyman, Princeton, NJ, United States

We will describe on-going work of efficient routing of intermodal traffic - using both truck and rail (and possibly water routes within the U.S.), and the calculations of resulting green-house-gas emissions.

4 - Energy and economic impacts of advanced freight transportation concepts

Olcay Sahin, Argonne National Laboratory, Lemont, IL, United States

In 2021, the transportation sector significantly contributed to greenhouse gas emissions. Medium and heavy-duty vehicles (MHDVs), primarily responsible for U.S. freight movement and expenses, pose environmental challenges. In line with the U.S. goal of net-zero carbon emissions by 2050, advanced freight transportation concepts play an important role energy and economic impacts. Adoption of alternative fuels such as hydrogen, biofuels, or electricity can reduce reliance on fossil fuels, thereby decreasing greenhouse gas emissions and mitigating environmental impact. Improved efficiency in freight transportation often leads to lower operational costs for businesses, including reduced fuel expenses and maintenance costs. This can result in higher profit margins or more competitive pricing for consumers. To quantify the potential of advanced freight transportation concepts when deployed at scale at the system level, the DOE SMART Mobility workflow is implemented (e.g., POLARIS, SVTrip, Autonomie), leveraging multiple metrics including mobility, energy, emissions, and cost.

Behavioral Perspective of Operations: Adapting to a Changing World

Invited Session

Behavioral Operations Management

Chair: Lei Hua, University of Texas at Tyler, Tyler, TX, United States

1 - The Market Value of Social Responsibility Communications: a Cross-Cultural Behavioral Study

Lei Hua, University of Texas at Tyler, Tyler, TX, United States, Tim Kraft, Doug Thomas, Yanchong Zheng

With consumers' increasing expectation for transparency, companies need to understand how to effectively communicate information about their supply chain practices. Our study examines consumers' valuations of sustainability communication and the impact of different social responsibility topics and message formats on these valuations.

2 - Assessing Consumer Reactions to Sustainable Supply Chain Disclosures: A Comparative Study Using Likert Scales and Brain Computer Interfaces

Yanji Duan, University of North Florida, Jacksonville, FL, United States, Qingyun Zhu, Feng Liu

In the evolving landscape of sustainable operations, businesses are increasingly adopting practices that prioritize environmental and social responsibility. Central to this movement is the concept of sustainability supply chain disclosure, which enhances transparency and accountability. By openly communicating their sustainability initiatives along their supply chains, firms enable consumers, who are increasingly driven by sustainability values, to make informed purchasing decisions. Within this context, cognitive appraisal theory offers a framework to understand consumer reactions to sustainability disclosures. It suggests that consumers' cognitive evaluations of products and services influence their emotional and behavioral responses, affecting decisions and behaviors like purchase intentions and brand attitudes. However, the primary method for assessing these emotions, the Likert scale, has limitations due to its reliance on self-reporting and the subjective nature of emotions. This research proposes to bridge this gap by combining traditional Likert scales with Electroencephalography (EEG) to capture genuine, real-time emotional responses. This innovative approach seeks to answer key questions about the consistency of results between Likert scales and EEG measurements, the precision of EEG in revealing emotional responses, and ways to enhance Likert scales using EEG findings. This study will conduct two behavioral experiments, one online scenario-based and the other in a lab using EEG, to examine consumer responses to sustainable supply chain disclosures.

3 - A Data-Driven Approach to Assortment Planning for Collective-Intelligence Crowdsourcing Contests with Heterogenous Participant Motivations

Olumurejiwa Fatunde, University of Toronto, Toronto, ON, Canada, Gonzalo Romero

Many organizations have increasingly adopted novel methods of organizing distributed workers, including crowdsourcing. This paper studies how strategically-selected contest offerings that incorporate user motivation can improve crowdsourcing for skilled work in a setting focused on collective, rather than individual, performance. We explore two questions: first, we seek to learn from historical data the underlying motivations that drive participation on distributed-task platforms. Second, we determine the optimal assortment of contests to offer each motivation-based class. We use data from a healthcare platform that runs rank-order tournaments to collect and aggregate diagnostic opinions, and that can tailor contest offerings and prizes to attract users and shape behavior. As medical misdiagnosis can have fatal consequences, innovative models that improve diagnostic accuracy or facilitate incorporation of external expertise can transform healthcare. We borrow from the dynamic assortment planning literature by framing the contest offering decision as an assortment problem with independent search, perishable goods, and dependent demand. We treat motivation as a latent variable and apply a finite mixture model to historical performance data to understand whether users are primarily motivated by learning opportunities, monetary prizes, or affinity for competition. We determine the optimal assortment, balancing motivation-specific user utility and platform goals. Data-driven estimates provide greater insight into user motivation than self-reported responses and reduce the number of contests offered by 38%, simplifying the user experience without increasing cost. Users who had previously entered contests included in their streamlined assortments achieved above-average performance, suggesting the ability to systematically eliminate poor performance.

4 - Fair Funnels: How Hiring Processes (and Interventions) Impact Di-Versity and Quality

Eunjee Kim, UW-Madison, Madison, WI, United States, Jordan Tong, Xiaoyang Long

Behavioral research has uncovered several biases that evaluators display when judging quality. How do these biases impact the diversity and quality of hires? We examine this question using a stylized model of recruiting structures, i.e., the funnel shape from the candidate pool to the final hire(s), and the hiring committee composition. We show that the impact of judgment biases depends critically on the recruiting structure. Whereas a basic model of taste-based discrimination leads to intuitive dynamics, incorporating other established biases like outgroup homogeneity and judgment noise can lead to surprising results. We deliver insights into what combinations of judgment biases and recruiting structures most (dis)advantage minorities, and how organizations can change their recruiting structure to improve both quality and diversity.

Co-Chair: Yash Kanori, Columbia, New York City, NY, United States

1 - Markov Persuasion Processes with Endogenous Agent Beliefs

Krishnamurthy Iyer, University of Minnesota, Minneapolis, MN, United States, Haifeng Xu, You Zu

We study a Markov persuasion process, where a long-lived principal ("sender") persuades a stream of short-lived agents by sharing information about an evolving state. The state transitions are Markovian and the sender seeks to maximize the long-run average reward by committing to a (possibly history-dependent) signaling mechanism. While most previous studies of Markov persuasion consider agents with exogenously specified beliefs, we study a more natural variant with endogenous beliefs that depend on the chain's realized history. A key challenge in studying this variant is to model the agents' partial knowledge about the history. We focus on settings where each agent observes the history with a k period lag. We show that the sender's long-run average payoff (weakly) increases with the lag, and provide efficient LP formulations to compute the optimal signaling mechanisms for k = 0 (full history information) and k = infinity (no history information). We also find sufficient conditions under which sender's optimal payoff is the same regardless of the lag with which the agents observe the history. For general values of the lag, we identify challenges in formulating the sender's problem, and provide a bilinear optimization framework to solve a restricted problem. Finally, using robust persuasion, we design simple signaling mechanisms that are approximately optimal when the lag is large.

2 - Incentives for Exploration at Market Equilibrium

Vijay Kamble, University of Illinois Chicago, Chicago, IL, United States

Online marketplaces face an exploration problem: the qualities of new supply units are unknown and must be discovered through customer feedback so that higher-quality supply gets prioritized for matching. However, customers are generally myopic and unwilling to participate in exploratory matches, leading to the well-known concern of incentivizing such exploration. This paper uncovers the role of competitive pricing effects arising from market congestion in creating incentives for exploratory behavior among myopic customers. The intuition is that since established higher-quality supply units are expected to be more popular and, hence, more congested, they naturally demand higher prices at a competitive equilibrium than new supply units, effectively incentivizing customers to explore. This paper presents a comprehensive analysis of the extent to which this intuition holds and exogenous incentives for exploration are necessary for such markets. To investigate this question, we define a competitive equilibrium notion for markets with evolving public information about supply units. The key result establishes that, under a tightly characterized market regularity condition, the ratio of equilibrium matching value to the system optimal value is bounded by the aggregate congestion level, indicating that congested regular markets inherently incentivize exploration. Furthermore, we show that in markets with linear information transition structures, the equilibrium achieves the first-best system-optimal value regardless of the congestion level. Finally, we address the problem of designing optimal price interventions to align market equilibrium with the system-optimal solution. Overall, our results inform market designers grappling with the concern of incentivizing exploration in various online marketplaces.

3 - Information Design for Spatial Resource Allocation

Manxi Wu, Cornell University, ORIE, ITHACA, NY, United States, Ozan Candogan

In this paper, we study platforms where resources and jobs are spatially distributed, and resources have the flexibility to strategically move to different locations for better payoffs. The price of the service at each location depends on the number of resources present and the market size, which is modeled as a random state. Our focus is on how the platform can utilize information about the underlying state to influence resource repositioning decisions and ultimately increase commission revenues. We establish that in many practically relevant settings a simple monotone partitional information disclosure policy is optimal. This policy reveals state realizations below a threshold and above a second (higher) threshold, and pools all states in between and maps them to a unique signal realization. We also provide algorithmic approaches for obtaining (near-)optimal information structures that are monotone partitional in general settings.

4 - Optimal Signaling Mechanism under Demand Variation and Customers with Heterogeneous Patience

Prakirt Jhunjhunwala, Columbia Business School, New york, NY, United States, Jing Dong, Yash Kanoria

In an unobservable queue, where customers lack complete wait time information, a throughput-maximizing server aims to exploit the information asymmetry by strategically signaling coarse congestion information to incentivize customers' arrival into the system. In this work, we characterize the structure of the optimal information-sharing mechanism used by the server by adopting a Bayesian persuasion framework to model the customers' response to the provided signal. We incorporate two important real-world features, introducing additional information asymmetries between servers and customers. Firstly, we explore customer heterogeneity with private types, where customers vary in willingness to wait, modeled using the utility function. Secondly, we consider demand variation, where the customer arrival rate varies from one day to the next and is only observable to the server. We model the server's throughput optimization problem as an infinite dimensional linear program in terms of steady-state distribution. We also develop an equivalent Constrained Markov Decision Process (C-MDP) formulation. Both formulations offer insights into the properties of the signaling structure.

Customer heterogeneity works in favor of the customers, allowing some customer classes to receive strictly positive utility under private customer types. We discover a counter-intuitive phenomenon where the optimal signaling mechanism has a laminar structure; for example, with two customer types, the interval of queue lengths in which only patient customers enter is nested within the queue length intervals in which all customers enter. In contrast to customer heterogeneity, demand variation favors the server by providing additional flexibility due to the customer's lack of accurate arrival rate information.

Rare Events and Large Deviations

Invited Session

Applied Probability Society

Chair: Fiona Sloothaak, Eindhoven University of Technology, Eindhoven, Netherlands

1 - From Heavy-Tailed Rare Events to Global Dynamics

Chang-Han Rhee, Northwestern University, Evanston, IL, United States, Xingyu Wang

We discuss how heavy-tailed large deviations asymptotics can characterize the nominal global dynamics.

2 - On the first passage times of spatial branching processes in R^d

Zhenyuan Zhang, Stanford University, Stanford, CA, United States, Jose Blanchet, Wei Cai, Shaswat Mohanty

Spatial branching processes, including branching Brownian motion, branching random walks, and their variants, have a long history in probability and a wide range of applications in ecology, population biology, and modeling epidemics. In this talk, we initiate the study of their first passage times (FPT), by considering the FPT to a ball of radius one with a distance x from the origin, in a Euclidean space of an arbitrary dimension. We establish precise asymptotics of the first passage times as a function of x. We also discuss interesting consequences in polymer physics. This is based on joint work with Jose Blanchet, Wei Cai, and Shaswat Mohanty.

3 - Decision-Making under Extreme Risks: Configuring Optimization Algorithms for Rare-Event Optimization

Wasin Meesena, Columbia University, New York, NY, United States, Henry Lam

We consider stochastic optimization where the goal is not only to optimize an average-case objective, but also mitigate the occurrence of rare but catastrophic events. This problem, which is motivated from emerging applications such as safe AI, requires an integration of variance reduction into sampling-based optimization algorithms. These variance reduction techniques, widely studied for estimation tasks, helps sharpen the accuracy of the associated empirical estimates in the algorithm with the hope of guaranteeing a realistic optimization runtime. Despite the reasonableness of this approach, we demonstrate how a variance-reduction-optimization integration, even executed in an adaptive fashion studied by recent works, encounters fundamental challenges when using stochastic gradient descent procedures. On a high level, the challenge arises from the extreme sensitivity of tail-based objectives with respect to the decision variables, which renders the failure of traditional Lipschitz-based analyses. We offer some potential remedies and supporting numerical results.

4 - Scale-free cascading failures: Generalized approach for all simple, connected graphs

Agnieszka Janicka, Technical University Eindhoven, Eindhoven, Netherlands, Fiona Sloothaak, Maria Vlasiou

Cascading failures, wherein the failure of one component triggers subsequent failures in complex interconnected systems, pose a significant risk of disruptions and emerge across various domains. Understanding and mitigating the risk of such failures is crucial to minimize their impact and ensure the resilience of these systems. In multiple applications, the failure processes exhibit scale-free behavior in terms of their total failure sizes. Various models have been developed to explain the origin of this scale-free behavior. A recent study proposed a novel hypothesis, suggesting that scale-free failure sizes might be inherited from scale-free input characteristics in power networks. However, the scope of this study excluded certain network topologies. Here, motivated by power networks, we strengthen this hypothesis by generalizing to a broader range of graph topologies where this behavior is manifested. Our approach yields a universal theorem applicable to all simple, connected graphs, revealing that when a cascade leads to network disconnections, the total failure size exhibits a scale-free tail inherited from the input characteristics. We do so by characterizing cascade sequences of failures in the asymptotic regime.

Microeconomics, from a Computer Science Perspective

Invited Session

Applied Probability Society

Chair: Kangning Wang, 94305

1 - Deterministic Budget-feasible Clock Auctions

Daniel Schoepflin, Rutgers University, New Brunswick, NJ, United States

We revisit the well-studied problem of budget-feasible procurement, where a buyer with a strict budget constraint seeks to acquire services from a group of strategic providers (the sellers). During the last decade, several strategyproof budget-feasible procurement auctions have been proposed, aiming to maximize the value of the buyer, while eliciting each seller's true cost for providing their service. These solutions predominantly take the form of randomized sealed-bid auctions: they ask the sellers to report their private costs and then use randomization to determine which subset of services will be procured and how much each of the chosen providers will be paid, ensuring that the total payment does not exceed the buyer's budget. Our main result in this paper is a novel method for designing budget-feasible auctions, leading to solutions that outperform the previous auctions in multiple ways. First, our solutions take the form of clock auctions, and thus satisfy a list of very appealing properties, such as obvious strategyproofness, group-strategyproofness, transparency, and unconditional winner privacy, making these auctions much more likely to be used in practice. Second, in contrast to previous results that heavily depend on randomization, our auctions are deterministic. We provide an affirmative answer to one of the main open questions in this literature, asking whether a deterministic strategyproof auction can achieve a constant approximation when the valuation function is submodular over the services. This is joint work with Eric Balkanski, Pranav Garimidi, Vasilis Gkatzelis, and Xizhi Tan and originally appeared in a paper accepted at SODA 2022.

2 - Price Discrimination under Price Regulations

Yiheng Shen, Duke University, Durham, NC, United States, Kamesh Munagala, Renzhe Xu

In this presentation, I will talk about our recent study on third-degree price discrimination in a model first presented by Bergemann, Brooks, and Morris [2015]. Since such price discrimination might create market segments with vastly different posted prices, we consider regulating these prices, specifically, via restricting them to lie within an interval. Given a price interval, we consider segmentations of the market where a seller, who is oblivious to the existence of such regulation, still posts prices within the price interval. We show the following surprising result: For any market and price interval where such segmentation is feasible, there is always a different segmentation that optimally transfers all excess surplus to the consumers. In addition, we characterize the entire space of buyer and seller surplus that are achievable by such segmentation, including maximizing seller surplus, and simultaneously minimizing buyer and seller surplus.

This is joint work with Kamesh Munagala and Renzhe Xu.

3 - Breaking the Metric Voting Distortion Barrier

Prasanna Ramakrishnan, Stanford University, Stanford, CA, United States, Moses Charikar, Kangning Wang, Hongxun Wu

We consider the following well-studied problem of metric distortion in social choice. Suppose we have an election with voters and candidates who lie in a shared metric space. We would like to design a voting rule that chooses a candidate whose average distance to the voters is small. However, instead of having direct access to the distances in the metric space, each voter gives us a ranked list of the candidates in order of distance. Can we design a voting rule that, regardless of the election instance and underlying metric space, chooses a candidate whose cost differs from the true optimum by only a small factor (known as the distortion)? A long line of work culminated in finding deterministic voting rules with metric distortion 3, which is the best possible for deterministic rules and many other classes of voting rules. However, without any restrictions, there is still a significant gap in our understanding. Even though the best lower bound is substantially lower at 2.112, finding a randomized rule that guarantees distortion $3 - \epsilon$ for some constant ϵ has been a major challenge in computational social choice. In this work, we give a rule that guarantees distortion less than 2.753 by carefully randomizing between Maximal Lotteries, a natural game-theoretical voting rule dating back to the 60's, and new voting rules that we introduce. Based on joint work with Moses Charikar, Kangning Wang, and Hongxun Wu.

4 - The Secretary Problem with Predicted Additive Gap

Sherry Sarkar, Carnegie Mellon University, Pittsburgh, PA, United States, Alex Braun

The secretary problem is one of the fundamental problems in online decision making; a tight competitive ratio for this problem of 1/e has been known since the 1960s. Much more recently, the study of algorithms with predictions was introduced: The algorithm is equipped with a (possibly erroneous) additional piece of information upfront which can be used to improve the algorithm's performance. Complementing previous work on secretary problems with prior knowledge, we tackle the following question: What is the weakest piece of information that allows us to break the barrier? To this end, we introduce the secretary problem with predicted additive gap. As in the classical problem, weights are fixed by an adversary and elements appear in random order. In contrast to previous variants of predictions, our algorithm only has access to a much weaker piece of information: an additive gap. This gap is the difference between the highest and kth highest weight in the sequence. Unlike previous pieces of advice, knowing an exact additive gap (provably) does not make the problem trivial. Our contribution is twofold. First, we show that for any index k and any gap, we can obtain a competitive ratio of 0.4 (even if we do not know k), hence beating the prevalent bound for the classical problem by a constant. Second, a slightly modified version of our algorithm allows us to prove standard robustness-consistency properties as well as improved guarantees when knowing a range for the error of the prediction.

Award Session

Service Science

Chair: Weiwei Chen, Rutgers University, Piscataway, NJ, United States

1 - Innovative Resource Allocation in Public Services: Incorporating Utility Heterogeneity and Income Disparity

Siddharth Singh, University College London, London, United Kingdom, Owen Wu

Efficient and equitable allocation of a divisible resource and its associated costs or savings among consumers is a critical issue for many public service corporations, especially when consumers have heterogeneous incomes and private levels of resource utility. The challenge arises from the dual dimensions of consumer characteristics and the coupled allocation problems. Common approaches in practice often ignore utility heterogeneity or income disparity, leaving a significant gap between potential and actual outcomes. We develop and analyze a resource allocation method to bridge this gap. Our model incorporates consumer heterogeneity in both income levels and private utility from the resource. We formulate the problem of allocating the resource and its associated costs or savings, aiming to maximize aggregate welfare. We propose a method that offers consumers income-dependent menus (IDM) of quantity and cost (or savings) options, and uncover key structural properties of these menus. Our IDM approach significantly outperforms the considered alternatives in numerical studies calibrated using real-world data. In the realm of resource allocation where both income and resource utility levels are heterogeneous, significant welfare gains can be realized by judiciously leveraging the dual dimensions of heterogeneity. Implementing our IDM approach ensures that consumers receive and contribute to resources in a manner that reflects their financial capacities and utility levels, maximizing overall welfare.

2 - Racial and Gender Biases in Customer Satisfaction Surveys: Evidence from a Restaurant Chain

Masoud Kamalahmadi, University of Miami, Coral Gables, FL, United States, Qiuping Yu, Yong-Pin Zhou

Racial and gender inequalities are ubiquitous in the workplace. Whereas previous studies have primarily focused on employer discrimination, we study the role of customers, using 1.5 million transactions and 260,000 customer satisfaction surveys from a full-service casual-dining restaurant chain in the US. We find that customer ratings of servers are biased against racial minority, and, interestingly, also against female servers despite their majority in this occupation. We further find evidences that suggest that statistical discrimination is the primary driver for racial biases, while status-based discrimination is likely the main driver for gender biases. Given these underlying mechanisms, we propose tailored strategies to mitigate the biases.

3 - Online Fair Allocation of Perishable Resources

Chamsi Hssaine, University of Southern California, Marshall School of Business, Los Angeles, CA, United States, Sean Sinclair, Siddhartha Banerjee

We consider a variant of the canonical online fair allocation problem: a decision-maker has a budget of perishable resources to allocate over a fixed number of rounds. Each round sees a random number of arrivals, and the decision-maker must commit to an allocation for these individuals before moving on to the next round. The goal is to construct a sequence of allocations that is envy-free and efficient. Our work makes two important contributions toward this problem: we first derive strong lower bounds on the optimal envy-efficiency trade-off that demonstrate that a decision-maker is fundamentally limited in what she can hope to achieve relative to the no-perishing setting; we then design an algorithm achieving these lower bounds which takes as input a prediction of the perishing order, and a desired bound on envy. Given the remaining budget in each period, the algorithm uses forecasts of future demand and perishing to adaptively choose one of two carefully constructed guardrail quantities. We demonstrate our algorithm's strong numerical performance - and state-of-the-art, perishing-agnostic algorithms' inefficacy - on simulations calibrated to a real-world dataset.

4 - The Dedicated Docket in U.S. Immigration Courts: An Analysis of Fairness and Efficiency Properties

Daniel Freund, MIT, Cambridge, MA, United States, Wentao Weng

The dedicated docket was introduced by the Biden Administration to reform the immigration system. It creates a separate queue for immigration proceedings where judges are supposed to issue decisions for each case within a target timeframe. Its goals are to improve speed, accuracy, and fairness. Though it meets its first goal, legal advocacy groups report that this comes at the expense of the last. Referring to it as a ``Denial of justice'', they find that cases on the dedicated docket routinely fail to access legal representation, and have a much lower asylum grant rate. Against this backdrop, we study the operational implication of the dedicated docket.
We develop a queueing model wherein a policy maker (PM) routes asylees to the regular or the dedicated docket, and sets a delay target for the latter. Constrained by the target, the court allocates its capacity to minimize the average delay. Immigration lawyers schedule their time between dockets to maximize the rate of successful asylum cases. Compared to a single docket, we show that the dedicated-docket system can Pareto-improve the speed and accuracy. However, we also prove that the dedicated docket system satisfies two natural fairness rules only if it is dominated by the single docket.
Our analysis can inform the public discourse. We prove that the lack of fairness is a fundamental design flaw of the new program. Though delay differentiation enables a surprising efficiency gain, this requires unfairness between. Policy makers and legal advocacy groups should be aware of such tradeoffs.

5 - The Power of Simple Menus in Robust Selling Mechanisms

Shixin Wang, The Chinese University of Hong Kong, Hong Kong, China, People's Republic of

We study a robust selling problem where a seller attempts to sell one item to a buyer but is uncertain about the buyer's valuation distribution. Existing literature shows that robust screening provides a stronger theoretical guarantee than robust deterministic pricing, but at the expense of implementation complexity, as it requires a menu of infinite options. Our research aims to find simple mechanisms to hedge against market ambiguity effectively. We develop a general framework for robust selling mechanisms with a finite menu (or randomization across finite prices). We propose a tractable reformulation that addresses various ambiguity sets of the buyer's valuation distribution, including support, mean, and quantile ambiguity sets. We derive optimal selling mechanisms and corresponding performance ratios for different menu sizes, showing that even a modest menu size can deliver benefits similar to those achieved by the optimal robust mechanism with infinite options, establishing a favorable trade-off between theoretical performance and implementation simplicity. Remarkably, a menu size of merely two can significantly enhance the performance ratio compared to deterministic pricing.

Critical issues in Pharmaceutical Value Chains

Invited Session

Health Applications Society

Chair: Hui Zhao, The Pennsylvania State University, University Park, University Park, PA, United States

Co-Chair: Ji Won Moon, Pennsylvania State University, University Park, PA, 16802, United States

1 - Impact of Copay Accumulator Ban: Evidence from National Healthcare Utilization Data

Ji Won Moon, Pennsylvania State University, University Park, PA, United States, Hui Zhao, Susan Lu

The recent federal ruling for a nationwide ban on copay accumulator represents the latest development in a decade-long game of cat and mouse in the pharmaceutical industry. The accumulator ban aims to undo the insurer’s restrictions on copay assistance programs designed to promote sales of pricey brand drugs among commercially insured patients. The ban poses uncertainties regarding ensuing market responses that have not been studied. We address the following questions: What impact does the ban have on drug purchase quantity, patient and insurer cost burdens, and the total volume of patients on therapy? What is the ban’s impact on health equity? What stakeholder responses does the ban trigger, and what do they imply about its long-term consequences?

2 - Does Production Location Impact Medication Quality? An Empirical Study on the Effectiveness Variations

Jun Li, Ross School of Business, University of Michigan, Ann Arbor, MI, United States, Xinyu Liang, Ravi Anupindi, In Joon Noh

Global production offers promising avenues for cost reduction but introduces challenges in maintaining consistent quality standards. We study the health effects of medications produced in over 1,000 pharmaceutical manufacturing facilities with over ten million annual prescription patients. Utilizing a large-scale dataset that includes patient-level and production facility-level data, we assess the impact on patients with medication prescriptions for nine conditions. Our empirical analysis reveals significant outcome variations across different manufacturers and production countries and explores potential mechanisms behind these variations. Our study offers insights for regulatory bodies on optimizing inspection procedures and ensuring consistent quality control across borders to safeguard public health.

3 - Pharmaceutical Supply Chain Design Considering Export Bans Induced by Capacity Strains

Martha L. Sabogal De La Pava, Clemson University, Clemson, SC, United States, Emily Tucker

For decades, pharmaceutical supply chains have faced persistent challenges in meeting domestic and global drug demand. Challenges include exposure to multiple types of disruption risks, which are capable of causing failures in the supply chain operation. These failures may lead to drug shortages, endangering patients' health and increasing the costs of healthcare systems. An emerging disruption risk, export bans, has increased due to recent geopolitical instability and persistent capacity strains. We propose a stochastic mixed integer program for global supply chain design that considers disruption risks, such as export bans, correlated natural disasters, and facility quality issues. Global capacity strains induce export bans. A natural disaster may affect countries in proximity. Operational strains such as uncertainty in demand and supplies are also included. We analyze the impact of such disruption risks on optimal supply chain structures and global drug shortages.

4 - Assortment Optimization of Prescription Coupons for Online Discount Programs

Yishen Cai, University of Miami Herbert Business School, Miami, FL, United States, Nan Yang, Hongmin Li

We consider an assortment problem motivated by online prescription-drug discount programs. Coupon vendors such as GoodRx (GDRX) provide discount card for prescription drugs by partnering with Pharmaceutical Benefit Managers (PBMs) and leveraging PBMs' negotiated prices with retailers and manufacturers. GoodRx uses its online platform to list discounted prices for prescription drugs at each participating pharmacy and direct individual patients to retail pharmacies through its listing. We study a coupon vendor's assortment problem of assigning available coupons at each retail pharmacy. The optimal decision must account for patients' choice among different retail pharmacies and balance the coupon vendor's commission revenue with patient benefit. The assortment problem is applicable to other digital marketers such as RetailMeNot, CapitalOneShopping and Goodshop. We propose an innovative and efficient solution approach for the optimal assortment and identify useful insights for decision support.

Models for Hospital Operations

Invited Session

Health Applications Society

Chair: A. Cecilia Zenteno, Massachusetts General Hospital, Boston, MA, United States

1 - Hospital Versus Home Care: Trading off Pre- and Post-Discharge Infection and Mortality Risks

Mor Armony, New York University, New York, NY, United States, Galit Yom-Tov

Previous research has shown that early discharge of patients may hurt their medical outcomes. However, in many cases the "optimal" length of stay (LOS) and the best location for treatment of the patient are not obvious. A case in point is hematology-oncology (blood cancer) patients, for whom these are critical decisions. Patients with blood cancer are susceptible to life-threatening infections after treatment. Sending these patients home early minimizes infection risk, while keeping them longer for hospital observation minimizes mortality risks if an infection occurs. We develop LOS optimization models for hematology-oncology patients that balance the risks of patient infection and mortality.

We develop a Newsvendor-style model to explore the impact of the infection and mortality risks on the optimal LOS from a single-patient perspective. We further consider the social optimization problem in which capacity constraints limit the ability of hospitals to keep patients for the entirety of their optimal LOS. Using a fluid model, we find that the optimal solution is a priority policy that is based on a speedup index. This policy may block some patients and immediately route them to home care, or speed up some patients' LOS and send them to be home-cared early after an observation period at the hospital.

In a case study, we show that around 75% of the patient population need some observation period. If the hospital is overloaded, using a speedup only policy is optimal for 90% of the patient types; applying it to all patients increases overall mortality risk by 0.5%.

2 - Heterogeneous Effect of Emergency Department Boarding on Inpatient Length of Stay

Xiaole (Alyssa) Liu, New York University Stern School of Business, New York, NY, United States, Jing Dong, Martin Copenhaver, Michael Hu, A. Cecilia Zenteno

Emergency Department (ED) boarding, the practice of holding admitted patients in the ED waiting for an available inpatient bed, is a common issue in many hospitals across the world. It is not only the primary cause of ED crowding but also raises patient safety concerns. When there are limited inpatient beds available, we need to decide how to prioritize the boarding patients in the ED for inpatient admission. In this work, we study the causal impact of boarding on inpatient length of stay (LOS). Using data from around 55,000 ED admissions and leveraging recent developments in double machine learning and causal forest with instrumental variables, we identify patient subpopulations that are affected by boarding differently. Through close collaboration with medical experts, we also identify potential explanations for the heterogeneous effects. This allows us to provide more actionable policy suggestions for boarding management and inpatient bed allocation.

3 - The Burden of Evidence for Operations Research in Hospitals

Martin Copenhaver, Johns Hopkins Hospital and Johns Hopkins University, Baltimore, MD, United States

What evidence is used to make strategic operational decisions in hospitals? In this talk, we will explore this question (and resulting challenges and opportunities) through a variety of examples. In particular, we consider the conceptual divide in medical versus operational decision making, how metrics of success can differ between hospital stakeholders and the academic community, and the implications for the practice of operations research.

4 - The Impact of Provider Behavior on Emergency Department Operations

Huifeng Su, Yale School of Management, New Haven, CT, United States, Lesley Meng, Rohit Sangal, Edieal Pinker

Emergency department (ED) providers play a crucial role in deciding patient admissions or discharges. Such decision-making significantly impacts the utilization of medical resources within the hospital, as it often relies on a range of shared diagnostic resources. Moreover, admitting patients contributes to ED crowding because they occupy ED spaces while awaiting transfer to downstream units. This study explores the behavior of physicians in making diagnostic decisions and the subsequent effects on ED congestion.

5 - Identifying Short-Stay Patients in the Emergency Department

A. Cecilia Zenteno, Massachusetts General Hospital, Boston, MA, United States, Thomas Kyle, Martin Copenhaver, Retsef Levi, Peter Dunn, Kyan Safavi, Gohram Baloch, Bethany Daily

Emergency Department overcrowding is a widespread patient safety concern. A significant contributor to this congestion is “boarding” patients who have been admitted but are waiting for an inpatient bed to become available. In this work, we propose establishing a different pathway for ED patients who are predicted to have a short length of stay upon admission (two nights maximum). Our goals are: to minimize disruptions in these patients' care path, to decrease the number of ED boarders, and to open up inpatient beds for more complex patients. We used xgboost to develop a predictive model using patients’ clinical, administrative, and demographic data and validated it with a group of physicians. The model has an out-of-sample AUC of 0.81, a precision of 69%, and is 75% accurate. This algorithm is in the process of being implemented at an academic medical center's ED.

Analytics Applications in Hospital Emegency Care

Invited Session

Health Applications Society

Chair: Abdulaziz Ahmed, University of Alabama at Birmingham, Birmingham, AL, 35294-1212, United States

1 - Enhancing Emergency Department Efficiency: Predictive Modeling for Patient Flow Metrics

Abdulaziz Ahmed, University of Alabama at Birmingham, Birmingham, AL, United States, Orhun Vural, Bunyamin Ozaydin, Khalid Aram, James Booth

ED overcrowding poses significant risks, including poor healthcare quality, increased medical errors, higher patient mortality, and low satisfaction. The American College of Emergency Physicians (ACEP) identifies this as a patient flow issue, suggesting that improving flow can mitigate overcrowding. In 2016, ACEP recommended the Full Capacity Protocol (FCP), which involves interventions based on real-time patient flow measures (PFMs) such as the number of patient waiting and boarded patients. This study aims to develop machine learning models to predict different PFMs including total patients in ED waiting rooms, average waiting times, total boarding patients, and average boarding times.

2 - Examining the Impact of Unfinished ED Laboratory Tests on Patient Throughput in Emergency Departments

Lu Wang, Ball State University, Muncie, IN, United States, Yajun Lu, Abdulaziz Ahmed

Laboratory testing during emergency department (ED) visits has been shown to directly influence patients' length of stay (LOS). However, the inappropriate utilization of laboratory resources has become an increasing concern. This study aims to examine the impact of laboratory tests ordered during ED visits but not utilized for physician diagnosis, referred to as "unfinished lab tests by disposition" (ULTD), on ED operations. After addressing potential endogenous factors, we empirically investigate how ULTD affects both ED LOS and inpatient LOS.

3 - Effects of long-stay patients on hospital capacity and flow: An empirical investigation

Esmaeil Bahalkeh, University of New Hampshire, Durham, NH, United States, Tze C Chiam, Yuehwern Yih

Often patients with discharge barriers stay in medical units for non-medical reasons and contribute to flow and capacity issues within and beyond medical units including intensive care units (ICU) and emergency departments. Using patient-level data at two academic hospitals within the same healthcare system, we estimate the impact of long-stay patients on length of stay (LOS) and 30-day readmission of other patients in medical units, as well as boarding time for patients transitioning from both ICU and step-down unit (SDU) to medical unit (MU). Inspired by prior studies on patient flow between ICU and MU, we include occupancy of origin (i.e., ICU, SDU) and destination (i.e., MU) units. We find that a larger proportion of long-stay patients in the MU result in shorter LOS for other patients in the MU, and longer boarding time for patients leaving the ICU to MU. Further, the proportion of long-stay patients is associated with neither 30-day readmission, nor boarding time for patients leaving the SDU. For both the ICU and the SDU, we find that patients experience shorter boarding time leaving these units to the MU as the unit gets busier. Finally, higher occupancy of the MU results in longer boarding time for patients leaving the SDU.

4 - Assessing the Impact of Clinical Symptoms on Emergency Room Capacity During the COVID-19 Pandemic: A Discrete Event Simulation Approach

Osama Aljarrah, Kettering University, Flint, MI, United States, Farnaz Ghazi Nezami

In this study, we have explored the role of clinical symptoms in managing the capacity of emergency room (ER) units during the COVID-19 pandemic by using commercial discrete event simulation (DES) software (FlexSim Healthcare). The focus is on understanding how variations in clinical symptom presentation impact ER operations and patient throughput under pandemic conditions. The ER unit at a hospital is modeled to assess key performance indicators (KPIs) in scenarios with varying degrees of COVID-19 symptom severity and incidence rates. The simulation defines and quantifies operational and capacity management indicators, such as wait times, resource utilization, and patient flow. Compared with a baseline non-pandemic model, multiple scenarios reveal a marked decrease in operational efficiency. Initial findings suggest that the presence of COVID-19 symptoms significantly impacts ER workflows, leading to increased occupancy rates and extended waiting times, thereby straining resources. The study emphasizes the necessity for effective triage protocols and capacity planning strategies tailored to pandemic circumstances to enhance ER responsiveness and mitigate the adverse effects on healthcare delivery. By providing a virtual replication of ER operations during the COVID-19 crisis, this analysis offers valuable insights for healthcare facilities aiming to optimize service levels and patient care in challenging times.

Operations Management and Marketing Interface

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: EunSu Lee, New Jersey City University, Jersey City, NJ, 07311, United States

Co-Chair: Hosun Rhim, Korea University Business School, Seoul, N/A

1 - A Conjoint Analysis Model with Attribute Groups: Focused on Music Streaming Services

Sangwon Eum, Korea University Business School, Seoul, Korea, Republic of, Hosun Rhim, Jeunghyun Kim, EunSu Lee

We develop a conjoint model based on attribute groups to effectively consider massive numbers of attributes. Previous research often faced challenges in measuring individual level utilities or required additional experiments to consider multiple attributes. A new method is developed and applied to music streaming services. Attributes are identified by text mining.

2 - Understanding the Concept of Proactive Quality Management and Its Profitability: The Event Study Method

Chongwoo Park, Korea University Business School, Seoul, Korea, Republic of, Hosun Rhim, Kim Yejee

Customers tend to defect when dissatisfied with the quality of products due to inconvenient experiences. To address this issue, we propose an innovative program called 'Proactive Quality Management.' We defined the concept of proactive quality management and deployed the event study method to measure its financial performance.

3 - Video Ranking Based on Reference Effect

Mengyan Zhu, Southeast University, Nanjing, China, People's Republic of, Ningyuan Chen, Qingwei Jin

By analyzing a public dataset from NetEase Cloud Music, we empirically verify that within short-form video platforms, where viewers can swipe down to see the next video, there exists an unconscious tendency for viewers to compare new videos with the best ones they have previously watched. Based on such empirical evidence, we study the sequential product ranking problem considering this peak reference effect. Traditional video recommendation literature typically ranks videos based on their popularity. However, our study takes into account the peak reference effect and finds that platforms should provide mediocre videos first and then gradually provide better videos to manage viewers' expectation. We consider both pre-set ranking scenario and responsive ranking scenario. Although the dynamics in the model make the problem challenging, we present structural results and design tractable algorithms with guaranteed performance for both scenarios.

4 - Enhancing AI Recommendation Services for Smarter Decisions: The Role of Standardization and Customization in Optimizing User Satisfaction

Sung Yeon Kim, Korea University, Sejong, Korea, Republic of, Jaeseok Yoon, Seonghyeon Han, Jinmin Kim

This research fundamentally rethinks how AI recommendation systems are evaluated, particularly emphasizing the strategic role of standardization. By adapting traditional metrics for information and system quality, the study evaluates how these metrics influence the performance and user reception of AI-driven recommendation tools. Central to this discourse is the influence of standardization as a critical moderator that substantially enhances recommendation quality and, consequently, user satisfaction. Through the application of structural equation modeling, this analysis highlights the significant benefits of aligning system outputs with standardized quality benchmarks, which in turn fosters enhanced user engagement. Furthermore, the research emphasizes the need for maintaining an optimal balance between standardization and customization. This balance is crucial for providing personalized recommendations that are not only impactful but also drive smarter decision-making processes. Overall, the findings promote a nuanced approach to the design and implementation of AI systems, advocating for standardized frameworks that enhance both the utility and acceptability of AI recommendations in various contexts.

Summit - 441

Emerging Topics in Platform Operations and Retail

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Dmitry Mitrofanov, Boston College, Chestnut Hill, MA, United States

1 - Wage Fairness in the Gig Economy

Jingyuan Wan, University of Michigan, Ann Arbor, MI, United States, Saif Benjaafar

We consider the impact of imposing fairness constraints on the wages that an on-demand service platform pays its workers. The platform draws on a pool of independent contractors (workers) with heterogeneous opportunity costs from one or more distinct groups. The workers decide whether or not to work for the platform and how much. The platform decides on the nominal wage it pays the workers, knowing that they are sensitive to both the nominal wage and how busy they expect to be, and the price it charges customers, knowing that they are sensitive to both the price and the delay they expect to experience. The platform can also choose to cap worker participation. We consider two notions of fairness: within-group fairness (in the form of a wage floor) and across-group fairness (in the form of a constraint on the wage difference between groups). In each case, we examine the impact of the fairness constraint on labor, consumer, and social welfare.

2 - Privacy-Preserving Data-Driven Inventory Management

Lorraine Yuan, Cornell Tech/Cornell University, New York, NY, United States, Elena Belavina, Karan Girotra

The use of customer data (demographics, past purchases, etc.) for inventory management can improve firm profits and customer service levels. Yet, large-scale use of such data increases the risks of breaching customers' privacy. This paper develops differential-privacy based privacy-preserving adaptations for three data-driven newsvendor pipelines: the usual two-step predict-then-optimize method, and two newer joint predict-and-optimize methods. We characterize the tradeoff among privacy loss, profits and consumer surplus for the privacy preserving versions of these three approaches. We show that both joint approaches outperform the two-step approach to preserve privacy: Obfuscating customer data can be done with less profit loss by considering downstream optimization problems, we can privatize outputs with less noise and more targeted noise injection.

3 - Dynamic Discrimination on Online Platforms

Peibo Zhang, Emory University , Atlanta, GA, United States, Xinyu Cao, Dennis Zhang, Ruomeng Cui

Prior studies on discrimination have revealed widespread racial discrimination on online platforms. In this paper, we examine how racial discrimination evolves over time. Using observational data from a large online education platform with more than 100,000 teachers in the United States, we tracked the daily openings and bookings of teachers during their first 12 weeks after joining the platform. We observed that African American teachers initially had more daily openings than White teachers but continued to receive fewer daily bookings. Utilizing a fixed-effect model, we show that the gap in daily bookings between White teachers and African American teachers increases by 6.38 times over the 12 weeks, equating to a 22% weekly increase. We further identified that the early accumulation of a repeated customer base and the reputation effect are the two key mechanisms driving this increase in discrimination. Additionally, we found no evidence that White teachers have a faster improvement in class quality compared to African American teachers. Our results underscore that past studies focusing solely on static discrimination may underestimate the true extent of discrimination over time.

4 - Gender Biases in Customer Satisfaction Surveys: Evidence from the Customer Service Center of An Online Retail Platform

Xiao Ni, Fudan Univerisity, Shanghai, China, People's Republic of, Qiuping Yu, Tianjun Feng, Yitong Wang

Using a large-scale data set of over 10 million interactions and about 1.5 million customer satisfaction surveys from an online retail platform in China, we study customers’ gender biases against workers and the mechanisms that drive such biases. We use the routing policy of the contact center as an exogenous shock, which allows us not only to causally identify customers’ gender bias against workers but also the mechanisms. In contrast to the literature which generally shows customers’ biases against male workers in female-dominated industries, our results show that customers are biased against female workers despite them being the majority among contact center workers. Specifically, such biases leads to 1.3% lower in customer ratings for female workers compared to male workers. The biases are more severe among customers from rural areas compared to those from big cities, which is consistent with status-based discrimination.

Summit - 442

Organ Transplantation 2

Invited Session

MSOM: Healthcare

Chair: Diwakar Gupta, University of Texas, Austin, TX, United States

1 - Are Faster Out-of-Sequence Utilization Decisions Beneficial?

Jingyao Huang, University of Missouri-Kansas City, Kansas City, MO, United States, Paola Martin, Diwakar Gupta

In the US, Organ Procurement Organizations (OPOs) procure deceased-donor kidneys, whereas Transplant Programs (TxPs) make utilization decisions for candidates listed at their centers. OPOs typically make offers for several candidates at the same time, which could be listed at multiple centers, in the strict priority sequence determined by national allocation rules. Higher-ranked candidates have the right of first refusal over lower-ranked candidates. TxPs are expected to utilize kidneys based on the merits of performing a transplant for each candidate independently of other candidates. However, they frequently utilize offered kidneys for lower-ranked candidates. This phenomenon is called list diving. The prevalence and impact of list diving on recipients' survival has been studied in the literature. However, in these papers, the speed with which a TxP made its utilization decision is not considered a factor. Based on evidence from the data, we first propose a time-based rule to identify a subset of utilization decisions that were out of sequence, and then evaluate their impact on the recipient and graft survival. The out-of-sequence transplants identified via the speed-based criterion are referred to as targeted placements (TPs). Thus, this study serves to show that quick out-of-sequence utilization decisions are neither better nor worse than all other utilization decisions. Similar to list diving, TPs shorten the time on dialysis for TP recipients while lengthening it for skipped candidates. However, contrary to our prior, they have no significant effect on the 1-year post-transplant patient and graft survival among either group of candidates.

2 - Pay-for-Performance Incentives in Organ Transplantation

Saumya Sinha, University of Minnesota, Minneapolis, MN, United States, Taewoo Lee, David Mildebrath, Andrew Schaefer, A Osama Gaber, Howard J Huang

Transplant programs in the US are subject to outcome-based regulations, whereby federal agencies evaluate them based on their patients’ post-transplant survival. Clinical evidence indicates that such regulations induce programs to reject high-risk transplant candidates to avoid penalization. We present a principal-agent model to analyze the incentives created by such regulations. We show that past regulations might have induced risk-averse patient selection. As an alternative, we propose a pay-for-performance reimbursement scheme that not only penalizes programs with below-average outcomes, but also pays a bonus to those with above-average outcomes. We demonstrate that the proposed scheme incentivizes programs to improve post-transplant outcomes, without inducing adverse patient selection.

3 - Optimization Models for Kidney Paired Donation (Kpd) with Desensitization Option

Michael Fu, University of Maryland-College Park, College Park, MD, United States, Xingyu Ren, Steven Marcus

Kidney transplantation is the definitive gold standard treatment for providing the best quality of life for end-stage renal disease patients, but there is a drastic shortage of kidney donors, both deceased and living. Furthermore, even for those patients with willing living donors, certain incompatibilities (e.g., blood type) may preclude transplantation. Two approaches for expanding access to transplantation are: (i) kidney paired donation (KPD), where transplant candidates swap their incompatible donor for a compatible donor; and (ii) desensitization therapy, where transplant recipients have their antibodies treated/removed. Currently, these schemes are predominantly administered in living-donor transplants and independently of each other, and the combinatorially hard KPD optimization is addressed using static deterministic models. A multi-university collaborative team of researchers from George Mason, Maryland, and Louisville are working on an integrated approach incorporating various optimization models. This talk will overview the entire project and then focus on one part: the individual organ acceptance decision.

4 - Optimal Desensitization Therapies for Kidney-Pairing Donations

Marwan Shams Eddin, George Mason University, Euless, TX, United States, Hadi El-Amine, Naoru Koizumi, Meng-Hao Li

Kidney transplantation stands as the quintessential treatment for end-stage renal disease, providing a superior quality of life for patients. However, accessibility remains a challenge due to the shortage of donors and issues of compatibility, particularly with ABO and HLA types. Current strategies such as kidney paired donation (KPD) and desensitization therapy address these challenges independently but face limitations. The decisions of pairing donors with recipients are fundamentally driven by the probability of recipients developing future diseases, (e.g., graft failures, cancer, among others) under specific treatments. In this work, we build a customized KNN machine learning model coupled with an optimization-based framework to determine desensitization treatments that reduce risks of undesired outcomes. Our results indicate that the customized treatments can reduce the risk of such outcomes.

1 - Operational Strategies for Customer Service: A Gatekeeper Framework

Maqbool Dada, Johns Hopkins University, Baltimore, MD, United States, Brett Hathaway, Evgeny Kagan

Customer service has evolved beyond in-person visits and phone calls to include live chat, AI chatbots and social media, among other contact options. Service providers typically refer to these contact modalities as “channels”. Within each channel, customer service agents are tasked with managing and resolving a stream of inbound service requests. Each request involves milestones where the agent must decide whether to keep assisting the customer or to transfer them to a more skilled – and often costlier – provider. To understand how this request resolution process should be managed, we develop a model in which each channel is represented as a gatekeeper system. We characterize the structure of the optimal gatekeeping policy and identify conditions under which threshold policies yield the optimal solution. We then turn to the broader question of strategic selection of an appropriate mix of service channels. We solve the channel mix problem for the special case where the service provider chooses among three channel architectures: live-agent-only, chatbot-only or both, and show that, in equilibrium, all three architectures may emerge as optimal.

2 - The Impacts of Recommendations on Consumption and Creation on Online Content-Sharing Platforms

Zhiyu Zeng, Washington University in St. Louis, St. Louis, MO, United States, Zhiqi Zhang, Dennis Zhang, Tat Chan

Online content-sharing platforms such as TikTok and Facebook, heavily rely on advanced algorithms to recommend user-generated content (UGC) to their users. These users can simultaneously consume and create UGC. Previous research has shown the content recommended by algorithms significantly impacts users' consumption habits; however, these recommendations can also affect users' motivation to create content, since they provide insights into the works of other content creators and generate peer effects. To study the impacts of recommendations on both consumption and production, we conducted a randomized field experiment on one of the world's largest online video-sharing platforms. In this experiment, we manipulated the popularity levels of the videos recommended by the algorithm. Our findings demonstrate that when users encounter recommended videos with lower popularity, their video-viewing time decreased by 1.38%. However, we also observed a substantial 2.39% increase in the number of videos uploaded to the platform. To understand and explain these results, we utilized a structural model that allows a user's incentive to create videos to be influenced by the "peer effect" captured by the relative popularity of recommended video creators and the user. We then used the estimation results of the structural model to conduct counterfactuals. Results reveal that recommending videos with high popularity is not always optimal when both content consumption and production are crucial to the platform. To maximize overall value, the algorithm should be tailored to recommend videos of varying popularity levels, better aligning with individual users' preferences for consumption and production.

3 - The Impact of Foster Care Payments on Child Placement Stability

Wani Zhang, London Business School, London, United Kingdom, Kamalini Ramdas

We examine the effect of monthly foster care payments on the placement stability of foster care children using data from the Adoption and Foster Care Analysis and Reporting System (AFCARS) during 2008-2021. We leverage the longitudinal nature of the dataset to assess how variations in payment levels affect placement stability, controlling for child-specific factors and employing an instrumental variable strategy to address potential endogeneity issues. We will present the main effects of the treatment as well as differential treatment effects, and we will discuss policy implications.

4 - The Granularity of Wait TIME Information: A Large-Scale Field Experiment on a Major Ride-Sharing Platform

Yiming Zhang, Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Qiuping Yu, Yong-Pin Zhou

Collaborating with a ride-sharing platform, we study whether and how the granularity of wait time information (WTI) impacts customers abandonment behavior through a randomized field experiment on our partner platform. In the experiment, we consider a point estimate, a narrow interval, and a wide interval as WTI. To uncover the fundamental mechanism, we propose a structural model to explore the impacts of WTI granularity on customers' prior beliefs and waiting cost-reward ratios. Through counterfactual studies, we explore how the design of WTI granularity impacts the performance of virtual queues. Additionally, we discuss the managerial implications of our findings.

5 - On state- and time-dependent service processes in healthcare

Hao Ding, Auburn University, Auburn, AL, United States, Sokol Tushe, Ruomeng Cui, Donald Lee

The empirical operations literature has shown that the service process of customers is state-dependent, with a primary focus on the relationship between patient length-of-stay (LOS) and workload in healthcare settings. However, the service process is also time-dependent because physician workload is not a static state, but varies continuously over the course of a patient's stay. By recognizing that the service process is both state- and time-dependent, we argue that the instantaneous service rate is the more natural quantity of interest in place of LOS. Conducting analyses based on the instantaneous service rate rather than LOS allows us to potentially resolve a longstanding question regarding the relationship between service speed and workload. Specifically, the empirical literature has identified contradictory findings among analyses based on LOS. We show, through the setting of an academic emergency department, that a consistent and intuitive relationship emerges when the analysis is based on the instantaneous service rate. We also use a naturalistic simulation to demonstrate meaningful performance gains from employing a service rate model to set staffing, relative to staffing according to results from analyses based on LOS.

1 - Phantom Capacity: Informational Cost of Multihoming on Ride-hailing Platforms

Kaitlin Daniels, Washington University in St. Louis, Olin Business School, Saint Louis, MO, United States, Jaelynn Oh

We study a ride-hailing market in which two platforms compete and drivers multihome. This environment produces information asymmetry that drivers can strategically exploit. When a driver is busy completing a ride for platform A, platform B does not observe that the driver is busy. The driver may strategically appear available to platform B (e.g. by logging into platform B's app) to increase the driver's utilization. We refer to drivers deploying this tactic as "phantom drivers." We derive phantom drivers' optimal strategy and quantify the inefficiency imposed on matching. We then compare to the alternative where platforms enforce single homing and describe the conditions under which platforms are willing to sacrifice the pooling benefits of multihoming to avoid the informational cost of phantom drivers.

2 - Solving Wild Goose Chase: Spatial, Temporal Pooling, and Service Region Reduction

Mingliu Chen, The University of Texas at Dallas, Richardson, TX, United States, Ming Hu

Wild Goose Chase is a phenomenon that may greatly hinder efficiencies in the ride-hailing context. A driver may drive a significant time for a pick-up but end up with a short ride. We propose implementing spatial, temporal pooling, and service region reduction to improve operational efficiencies in such systems. In spatial pooling, a driver only picks up riders at certain locations instead of chasing them around the city. However, riders must first walk to the pick-up location before getting served. We show that the pooling mechanisms may greatly improve operational efficiencies. The benefits critically depends on the rider's disutility of traveling on foot, the service radius, and whether the platform can endogenize the demand. With temporal pooling, a driver may not serve riders with the first-come-first-serve discipline. Instead, a driver can wait until certain riders are accumulated before serving them. By doing so, the expected pick-up distance for the closest rider decreases when the number of riders increases. Finally, the service region can be reduced to prevent long pick-up distances. However, we show that there exists a threshold and only above which, service region reduction is beneficial.

3 - No Call, No Show: Impact of No Show and Its Remedies on Service Platforms

Nil Karacaoglu, The Ohio State University, Columbus, OH, United States, Simin Li

With the surge in online-to-offline services, platforms face growing concerns about service provider no-shows, such as a handyman hired on Handy not showing up or a delivery person missing a mutually agreed time window. Customers may return to the platform after their own no-shows, but platforms risk losing those who experience service provider no-shows. Addressing no-show incidents is paramount for these platforms. Analyzing data from a European cleaning platform, we empirically assess how service provider no-shows impact customer retention. Our study shows that service provider no-shows increase the probability of customer attrition by 33.6%, with the negative impacts being more pronounced for more loyal customers. We further utilize a customer lifetime value model and show that the platform experiences a 4.2% loss in customer lifetime value due to no-shows. Subsequently, we study the effectiveness of two remedies for no-shows. We find no association between same-day rescheduling and no-show recovery, while offering a discount is positively linked to alleviating customer

attrition following no-shows. Lastly, we develop a model-based framework to suggest optimal remedy strategies, including offering discounts and maintaining a list of flexible standby cleaners to mitigate the negative impact of no-shows.

4 - Riding Through Rallies: Will You Tip More?

Wanjiang Deng, School of Management, Zhejiang University, Hangzhou, China, People's Republic of, Zhoupeng (Jack) Zhang, Ming Hu

Other than gig platforms' interventions, what "organic" factors can make customers treat gig workers (e.g., Uber drivers) in a more caring manner? In this paper, we approach this question by examining the impacts of the 2020 Chicago George Floyd protests on passengers' tipping behavior in the ride-hailing marketplace. We collect the ride-hailing data and deploy a year-to-year difference-in-differences analysis. We find that the protests not only increase the probability of passengers leaving a tip but also elevate the tip ratio by 2.98 percentage points. Nevertheless, this positive impact is attenuated on trips with less exposure to protest events and ebbs away two to three days after the protests concluded; it increases gig workers' incomes by a yet modest amount. By comparing with the taxi market, we identify a relatively weak social norm of tipping in the ride-hailing marketplace as one critical driving force: on the one hand, the weak norm makes passengers tip less generously and much less often in a ride-hailing market than they would in a taxi market; on the other hand, though, it also leaves space for event-specific and market-based factors to weigh in and (at least temporarily) affect passengers' behaviors. We propose two such factors that are potentially at play during the protests: passengers' empathy and platforms' disruption-aware services. Our work reveals how social movements may reshape customers' behaviors and, furthermore, shed light on the broader impacts of tipping as well as the platforms' role in fostering a tipping norm in the on-demand economy.

Invited Session

MSOM: Sustainable Operations

Chair: Tharanga Rajapakshe, University of Florida, Gainesville, FL, 32608, United States

Co-Chair: Na Zhang, Warrington College of Business, University of Florida, Gainesville, FL, United States

1 - Production Rationing Across Different Regulation Clusters: Carbon Emissions Perspective

Avinash Geda, University of North Carolina Wilmington, Wilmington, NC, United States, Nazli Turken

Supply chains still remain largely global, even after the vulnerabilities exposed after the recent disruptions. Lower costs of production and conducive regulation environments are the major contributing drivers. In the context of global supply chains, production could also get rationed across different geographical regions. From a carbon emissions perspective, different clusters could be subjected to different regulations, which directly plays into the production rationing decision. In this paper, we look at a firm's production rationing decisions across different geographical regulation clusters. When analyzing a firm's production rationing decisions within different regulation clusters, our focus is on understanding the influence of symmetric and asymmetric regulations on these decisions across two clusters. Symmetric regulations entail the same carbon emission regulation applied across clusters, while asymmetric regulations involve differing regulations in each cluster. By examining how firms allocate production resources in response to varying regulatory environments, we derive insights into the equilibrium production decisions. This research aims to uncover the underworking of production rationing strategies under different regulatory scenarios, providing insights for both policymakers and businesses.

2 - Non-Profit Support in Education: Resource Allocation and Students&Rsquo; Lifetime Outcomes

Harish Guda, Arizona State University, Tempe, AZ, United States, Goutham Takasi, Milind Dawande, Ganesh Janakiraman

An important determinant of the effectiveness of a non-profit organization is its resource-allocation strategy, i.e., how it assigns resources to its beneficiaries. Our work is motivated by resource allocation among nonprofit initiatives in which the outcome to a beneficiary depends on their effort, such as in education. In particular, we focus on nonprofit initiatives -- supported by an NPO -- that adopt a two-stage structure in allocating resources to its beneficiaries. The first-stage support is standardized and is provided to all beneficiaries, while in the second stage, the quality of support provided to the beneficiaries is contingent on their first-stage performance. Specifically, we assume that the NPO can provide a beneficiary with either a base-quality resource or a superior resource in the second-stage. The lifetime outcome of a beneficiary, a key component of the NPO's objective, is increasing in the beneficiary's effort in both the stages. Further, providing the beneficiary with the superior resource in the second-stage complements their effort and results in a better lifetime outcome as compared to providing the base-quality resource. We analyze the strategic role of an NPO's resource allocation strategy on the agent's effort and their lifetime outcome. We show why an NPO benefits from deliberately restricting access to resources, even in the absence of resource scarcity. Finally, we analyze the effect of resource scarcity and competition among the beneficiaries on their effort and lifetime outcomes.

3 - Strategies for Fair Food Distribution: Overcoming Uncertainty in Donations and Food Waste

Xianjia Gao, University of Illinois Urbana-Champaign Champaign, Champaign, IL, United States

Food bank, a non-profit humanitarian organization, secures charitable food donations through collaborative partnerships. Food banks are pivotal in mitigating food insecurity by distributing donations to those in need. However, they face several significant challenges. First, food banks depend on uncertain donations from diverse sources such as supermarkets, farms, food manufacturers, and individuals, leading to a highly variable supply. Second, the demand from partner agencies varies, complicating the equitable distribution of food. Moreover, approximately 35% of the distributed food (equating to about 29 million pounds annually) is perishable, making the management of food storage and distribution more complex. To address these challenges, we develop a multi-period dynamic model to help food banks allocate perishable food to agencies, aiming to maximize the value of the food, achieve equitable distribution, and minimize waste. We propose a heuristic algorithm based on fluid approximation with a provable regret upper bound. Furthermore, to tackle the dynamic environment, we further refine the heuristic through reoptimization and prove that the same regret bound can be achieved. Our results demonstrate that the proposed heuristics achieve asymptotic optimality with respect to the size of the food distribution network.

4 - Retailing Strategies of Imperfect Produce and the Battle Against Food Waste

Haoran Yu, Syracuse University, Syracuse, NY, United States, Burak Kazaz, Fasheng Xu

Edible but not-quite-perfect produce is often not sold in stores, leading to substantial food waste. The commercialization of imperfect produce constitutes a promising lever to tackle food waste. This study investigates how a grocery retailer should choose from three popular retailing strategies: discarding imperfect produce, bunching with cosmetically-perfect produce, and differentiating by selling perfect and imperfect produce separately at different prices. We adopt the multinomial logit choice model to derive consumers' demand and determine optimal decisions under each strategy. We compare three strategies and provide managerial insights to retailers about when each strategy should be used. We further examine two common policy interventions for reducing imperfect produce waste: relaxing grading standards to allow more imperfect produce to get into stores; and educating consumers on the value of imperfect produce. Our results suggest that policymakers should exercise caution in implementing these interventions because relaxing grading standards may shift food waste from farms to retail stores when the discarding strategy is optimal; and educating consumers about the value of imperfect produce can boost its consumption but may also lead to reduced sales of perfect produce due to cannibalization, potentially causing the retailer's shift to the discarding strategy and contributing to increased food waste. Our study also presents four extensions: upcycling the imperfect produce into by-products, endogenous pricing of imperfect produce, the mixed strategy that combines multiple popular retailing strategies, and the full-shelf ordering policies. The analyses of these extensions confirm the robustness of our main findings.

5 - Production Planning for Multiple Products Incorporating Emissions Trading

Ziyan Zhou, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Tong Wang, Jingwei Zhang

We consider a finite-horizon dynamic control problem where the manufacturer produces N products and satisfies random demands under a given total emission allowance level over the planning horizon. Meanwhile, the firm engages in managing the emission allowance by participating in the carbon trading market through transactions. We developed a heuristic policy that integrates emissions trading and production to minimize total cost, ensuring that its performance is within O(N^(1/2)) of the optimal solution.

Diverse Topics on Responsible Operations Management

Invited Session

MSOM: Sustainable Operations

Chair: Mahyar Eftekhar, Arizona State University, Tempe, AZ, United States

Co-Chair: Vanitha Virudachalam, Gies College of Business, UIUC, Champaign, IL, United States

1 - Behavioral Analysis of Needs Reporting and Fund Allocation in Humanitarian Response

Bengisu Urlu, INSEAD, Fontainebleau, France, Karen Donohue

When a disaster strikes, an accurate assessment of required funds for the response is crucial to utilize scarce resources for the greatest good. Humanitarian organizations (HOs) evaluate the needs and report the required amount of funds for their response operations. Donors then allocate their budget informed by these requirements. We represent this setting through a game theory model and explore how the type of information that the donor receives (e.g., targets for the number of people being served versus the cost of service per person) influences their allocations across HOs through experimental studies. We also examine how HOs form their reports under different information types, and the extent of their trustworthy behavior. Finally, we analyze the impact of these dynamics on humanitarian outcomes.

2 - The Production Benefits of Personalized Agricultural Advice: a Case Study of Mkrishi in Buland Shahar

Sriram Venkataraman, University of South Carolina, Columbia, SC, United States, Campbell Clarkson, Necati Tereyagoglu

We investigate the production effects of introducing mobile phone-based agricultural advice to farmers, using the launch of the mKrishi platform in Buland Shahar district in India. We find that, after a pilot of the mKrishi platform was launched in 2008, potato production in Buland Shahar increased by 3.93% relative to a synthetic control district. We then explore if such an effect could be explained by the changes in farmers' actions in three key agricultural inputs: cultivated area, chemical fertilizer usage, and irrigated area. We also show aggregate-level evidence of an increase in mobile phone usage in Buland Shahar after the launch of mKrishi, relative to the synthetic control, thereby suggesting the use of mKrishi by the farmers.

3 - Integrating Life Cycle Assessment into Supply Chain Optimization

Selin Hülagü, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, Wout Dullaert, Ayse Sena Eruguz, Reinout Heijungs, Dirk Inghels

Companies face increasing pressure from both government regulations and consumer demands to enhance the environmental sustainability of their supply chains. Life Cycle Assessment (LCA) appears to be one of the most promising approaches to systematically assess the environmental impacts of supply chains. LCA is typically performed for products for which decisions are already taken. Decisions on the network structure to bring products and/or services to customers are the typical focal point of supply chain network optimization (SCO). Existing literature handles LCA and SCO as separate sequential steps, leading to inconsistencies in scope and challenges in data transfer and rescaling. This research introduces a novel Supply Chain Life Cycle Optimization (SCLCO) model that integrates LCA and SCO. Our SCLCO model is based on LCA data structure and encompasses multi-time closed-loop SCO decisions (e.g. reverse chain management, inventory control, network design) while considering the three pillars of sustainability; environmental, economic, and social. It includes the harmonization of principles, terminology, and notation thereby bridging the gap between the LCA and SCO communities through a generalized formulation. Computational experiments on a selected SCO model from Operations Research literature validate the SCLCO, demonstrating its effectiveness in providing valuable insights to both LCA and SCO practitioners and researchers. Results emphasize that the simultaneous execution of LCA and SCO in SCLCO minimizes the risk of overlooking decision impacts and facilitates data transfer from existing LCA databases.

4 - Too Good to Go: Combating Food Waste with Surprise Clearance

Luyi Yang, University of California, Berkeley, Berkeley, CA, United States, Man Yu

We study a novel clearance mechanism of perishable goods to reduce food waste and increase store profit.

Summit - 447

Analytics for the Detection and Disruption of Illicit Supply Chains

Invited Session

Public Sector OR

Chair: Margret Bjarnadottir, University of Maryland, College Park, MD, United States

1 - Improved Lisa Analysis for Zero-Heavy Crack Cocaine Seizure Data

Eunseong Jang, University of Maryland, College Park, MD, United States, Margrét Bjarnadóttir, Marcus Boyd, S. Raghavan

Local Indicators of Spatial Association (LISA) analysis is a useful tool for analyzing and extracting meaningful insights from geographic data. It provides informative statistical analysis that highlights areas of high and low activity. However, applying LISA analysis methods to zero-heavy data may not be appropriate, as without the correct mathematical context the meaning of the patterns identified by the analysis may be distorted. We highlight these issues through statistical analysis and provide the appropriate context for interpreting LISA results for zero-heavy data. We then propose an improved LISA analysis method for spatial data with majority zero values. Applying our proposed methodology to crack cocaine seizure data in the U.S., we demonstrate its benefits in zero-heavy contexts as well as finer categorization of observed data. As LISA analysis is a popular approach that supports policy analysis and design, and as zero-heavy data is common in these scenarios, our work provides a framework that is better tailored for result interpretation and an improved approach for zero-heavy geographic data, ultimately leading to better decisions.

2 - Large Language Models for Scalable Text Data Extraction and Analysis in the Context of Drug-Related Violence in Colombia

Shriyan Reyya, Montgomery Blair High School, Silver Spring, MD, United States, Margret Bjarnadottir, David Anderson, Galia Benitez

Extracting actionable information from large text corpora at scale has immense potential, ranging from improving business predictions and decisions to revolutionizing social science research. Historically, however, the cost of manual data collection and extraction has hindered the use of such databases. Large language models hold great promise in automating and accelerating this process. We demonstrate this potential, utilizing GPT-3.5 to extract information from a public dataset of 280,000 Colombian news articles focused on violent events occurring over four decades. After deduplication and verification, our dataset is more comprehensive than any other available data source, opening up a range of research possibilities. For example, we have studied the impact of forced coca crop eradication on violence, finding no significant impact, which conflicts with literature that has based its analysis on smaller data. Moreover, we have utilized the data for violence predictions and the study of criminal groups and their territories. The impact of our research is two-fold: firstly, we demonstrate the capability of large language models in scalable text data extraction; secondly, in the context of Colombia, our data and results challenge current literature and stand to assist in informing public policy.

3 - Analyzing Illicit Drug Supply Chains: A Cocaine Case Study

S. Raghavan, University of Maryland, College Park, MD, United States, Galia Benitez, Margret Bjarnadottir, Siddharth Chandra, Greg Midgette

We report on an interdisciplinary effort of analyzing illicit drug supply chains. Our work has focused on illuminating the structure of illicit drug supply chain networks, quantifying the impact of disruptions on the drug supply chain and building models to support disruption strategies of anti-narcotics and other agencies. In this talk we will summarize some of our key findings and approaches.

4 - Analytical Methods to Identify Broad Patterns in the Commercial Sex Ad Ecosystem

roya shomali, The University of Alabama, Tuscaloosa, AL, United States, Nickolas Freeman

Sex traffickers use the internet to exploit individuals through online commercial sex advertisements (sex ads). Analyzing sex ad data to derive actionable insights poses significant challenges due to the high volumes of ads, the prevalence of scam ads, and the presence of generic or ambiguous data points that introduce noise. Consequently, there is a limited understanding of the individuals represented in these ads and the hidden patterns they follow. This research develops and analyzes a comprehensive set of features to uncover broad categories of individuals engaged in the online commercial sex ecosystem. Our methodology integrates techniques from natural language processing and network science to analyze individual behaviors in sex ad data, focusing on movement patterns, linguistic choices, and posting behaviors. We employ a binary classification framework to estimate the similarity between individuals, thereby quantifying their degree of similarities. We then use graph-based community detection methods to identify distinct clusters of individuals within the online ecosystem with high similarity among individuals in the same cluster. Our goal is to uncover insights regarding the complex patterns obscured within the data that can support counter-trafficking agencies by revealing how different individuals or groups, potentially across various regions, operate within this illicit network. This research advances academic discourse in trafficking analysis and provides scalable, practical tools that meet the diverse needs of real-world applications. These tools offer crucial support to law enforcement and policymakers, enabling more informed strategies to combat sex trafficking.

Summit - 448

Optimization for Real People

Invited Session

Minority Issues Forum

Chair: Alexandra Newman, Colorado School of Mines, Golden, CO, 80401, United States

1 - Comparative Performance of Battery- and Diesel-Powered Haulage Fleets in Underground Mines

Aaron Swift, Colorado School of Mines, Golden, CO, United States

Battery-electric vehicles have the potential to improve ambient conditions in underground mines by reducing the amount of heat and diesel exhaust emitted. Existing literature considers the differences in cost, heat load, and productivity between individual diesel and battery vehicles; this study uses simulation techniques to determine the effect of electrifying an entire haulage fleet on the overall heat load, emissions, and energy usage of an underground mine as activities take place deeper in the earth. This information is important for mine operators to assess vehicle electrification as a means to achieve greenhouse gas emissions reduction targets.

2 - Optimizing Vehicle Fleet Composition in Underground Mines

John Ayaburi, Colorado School of Mines, Golden, CO, United States, Aaron Swift, Jason Porter , Andrea Brickey , Alexandra Newman

Underground mine planning uses production schedules to determine a (near-)optimal sequence of activity execution to maximize net present value while considering resource limitations and spatial precedence. At the time of this writing, the mining industry relies heavily on the use of diesel-powered equipment, which accounts for heat accumulation and exhaust emissions that can create unsafe conditions in the work environment. Sustainable mining practices call for the transition from diesel- to battery-powered equipment. We present a large-scale production scheduling model that (i) prescribes activity start times in a medium-term schedule at daily fidelity, taking into account ventilation and refrigeration; and, (ii) determines a fleet composition, relative to a diesel-only fleet, that improves productivity. We implement an enumeration technique, embedded in our optimization model, whose special structure we exploit, to solve otherwise-intractable medium-term schedules to within 10% of optimality with solution times ranging from 145 seconds - 173,000 seconds. We find that the need for refrigeration is delayed and exhaust emission is reduced as more battery-powered equipment is introduced, showcasing the utility of battery vehicles in maintaining productivity and improving the safety of underground work environments. Our results provide schedules and fleet composition(s) that enhance the integration of battery vehicles into an operation. Our model provides a tool with which mine planners can make environmentally friendlier strategic decisions.

3 - Addressing School Accessibility Disparities in New York City: An Application of Vulnerability-Based Perspectives Through Computational Urbanism

Jose Ramirez-Marquez, Stevens Institute of Technology, Hoboken, NJ, United States, Rosario Contreras

This study investigates communities' vulnerability regarding school accessibility in New York City. Based on methods from systems reliability and computational urbanism, we analyze the spatial distribution of schools and their accessibility across different communities in the city. Our research aims to uncover significant disparities in school access, shedding light on potential inequalities in educational opportunities among diverse neighborhoods. By examining factors such as proximity, transportation infrastructure, and socioeconomic indicators, we provide insights into the spatial dynamics of educational accessibility. Our findings underscore the importance of addressing reliability, vulnerability, and resilience issues within urban contexts, particularly in critical areas such as education. Furthermore, we advocate for the wider adoption and integration of computational urbanism approaches within the research community to comprehensively understand and mitigate socio-spatial disparities, thus promoting the development of more equitable and resilient urban environments.

4 - Assessing Overall Performance of spORts Clubs and Decomposing into on-Field and off-Field Efficiency: An Application to Australian Rules Football

Don Galagedera, Monash University, MELBOURNE, Australia

Generally playing group management performance and financial management performance of sports clubs are assessed separately. We adopt a non-parametric methodology to assess overall performance first conceptualising overall management as a production process comprising of two serially-linked sub-processes; playing group management and financial management. Thereafter, we decompose overall performance to obtain estimates of performance at the sub-process level. Through this procedure it is possible to determine whether it is a sports club’s on-field performance or off-field performance or both may contribute towards its inefficiency, if any, in overall management. Further, a model is developed to determine targets for inefficient clubs to become overall efficient. The method is applied to 18 clubs in Australian rules football league. In 2021 season, the results reveal that on-field performance, on average, is better than off-field performance and variability in off-field performance is higher than that of on-field performance. Observed overall management inefficiency is mainly due to inefficiency in financial management. Results are robust to weighting scheme adopted in overall efficiency decomposition.

5 - Pilatus Aircraft Optimizes Inventory Management

Alexandra Newman, Colorado School of Mines, Golden, CO, United States, Garrett Miyaoka, Tulay Flamand

Pilatus Aircraft Ltd markets, sells, and maintains all Pilatus aircraft in North and South America, and seeks to improve customer service levels of all its repair parts, with an emphasis on "critical parts" orders associated with an aircraft-on-ground status. Using a hybrid methodology that combines a (Q,R) inventory stocking model with an optimization model that recommends antiquated parts to liquidate from its inventory, our tool improves the mix of parts held at the Broomfield warehouse to more quickly service customer orders. We describe actions that the company has taken to improve its service level factor, reduce its demand variability, and stabilize lead times across its supply chain for the sake of customer service.

1 - Optimizing Scheduling in Multi-Service Systems with Policy-Design Constraints: Application to University Mental Health Services

Hrayer Aprahamian, Texas A&M University, College Station, TX, United States

We present an optimization-based methodology for identifying time-varying scheduling policies, considering multiple customer classes with non-stationary arrival processes and realistic policy-design constraints. Initially, we analyze a simplified setting involving a single service type and introduce a novel approximation scheme to estimate the transient behavior of the stochastic system. By utilizing this scheme, we formulate the problem as a challenging mixed-integer nonlinear program. To address this problem, we employ a decomposition scheme to divide it into two more manageable subproblems, each of which presents a mixed-integer nonlinear program. By establishing key structural properties of the subproblems, we develop polynomial-time schemes that solve each of them to global optimality by casting them as more tractable shortest path problems. We then extend the solution scheme to accommodate multiple service types using a branch-and-bound-based method. To illustrate the effectiveness of our methodology, we perform a case study on college counseling centers. Our approach identifies scheduling policies that enhance students' access to vital mental health services by up to 52% over current practices, while utilizing the level of resources.

2 - Generating Data-Driven Clinical Role Models for Personalized Treatment Target Selection

Che-Yi Liao, Georgia Institute of Technology, Atlanta, GA, United States, Esmaeil Keyvanshokooh, Gian Garcia

Chronic diseases have a significant impact on global mortality rates and healthcare costs. Accordingly, clinicians may aim to determine treatment targets for individuals with chronic diseases to minimize the risk of adverse health events, using newly developed health tools, e.g., machine learning-based risk scoring tools. However, it is challenging to identify personalized treatment targets that are realistic, actionable, and robust to changes in the risk scoring tools by these tools alone. Additionally, persuading patients to take on the designed treatment plan can as well be difficult. To this end, we propose an approach named Data-driven Robust Clinical Role Model Selection (DR-CRS), incorporating two seemingly unrelated data sources maintained in the hospital. First, DR-CRS leverages the EHR database to find patients with similar health conditions and treatment plan. Second, it incorporates risk scoring tool records to mitigate the risk of failing to achieve treatment objectives. We develop an Active Learning Algorithm for Robust Role Model Selection (ALARRMS) and establish its exponential convergence rate. Utilizing two large and granular datasets, we illustrate the superior performance of DR-CRS compared to other benchmarks. Furthermore, we introduce two feature importance metrics to help clinicians understand how deviations from treatment targets can affect a patient's risk of adverse outcomes, thereby facilitating the design of appropriate treatment plans. Our findings highlight the effectiveness and practical relevance of DR-CRS in personalized treatment and clinical decision-making.

3 - Learning Personalized Treatment Strategies with Predictive and Prognostic Covariates

Andres Alban, Frankfurt School of Finance & Management gGmbH, Frankfurt, Germany, Stephen Chick, Spyros Zoumpoulis

We consider the problem of sequentially allocating sample observations to learn personalized treatment strategies, motivated by the design of adaptive clinical trials that aim to learn the best treatment as a function of patient covariates. In such settings, there may be clinical knowledge of which covariates are predictive (they may interact with the treatment choice) and which are prognostic (they may influence the outcome independent of treatment choice). We extend the expected value of information (EVI)/knowledge gradient (KG) framework to develop useful heuristics for a context with predictive and prognostic covariates. We show that several of our proposed allocation policies are asymptotically optimal in learning treatment strategies. When clinical knowledge is not available, we propose a Lasso method to adaptively learn which covariates are predictive and/or prognostic. Simulation experiments, motivated by applications for clinical trial design to assess potential personalized treatments of sepsis, show that our proposed policies can improve the efficiency of clinical trials to learn a treatment strategy.

4 - Using State Space Models for Personalized Lapse Prediction

Eric Pulick, University of Wisconsin - Madison, Madison, WI, United States, John Curtin, Yonatan Mintz

For individuals recovering from alcohol use disorders, lapse is an important precursor to relapse. Reliable lapse prediction is thus a prerequisite for healthcare providers seeking to effectively allocate scarce treatment resources. We consider a dataset of recovering patients who submitted once-daily ecological momentary assessments over a three-month study period. We demonstrate that state space models can be used to make effective lapse predictions compared to current population-level machine learning models.

5 - Methodology for Interpretable Reinforcement Learning for Optimizing Mechanical Ventilation

Joo Seung Lee, University of California, Berkeley, Emeryville, CA, United States, Malini Mahendra, Anil Aswani

Mechanical ventilation is a critical life-support intervention that uses a machine to deliver controlled air and oxygen to a patient's lungs, assisting or replacing spontaneous breathing. While several data-driven approaches have been proposed to optimize ventilator control strategies, they often lack interpretability and agreement with general domain knowledge. This paper proposes a methodology for interpretable reinforcement learning (RL) using decision trees for mechanical ventilation control. Using a causal, nonparametric model-based off-policy evaluation, we evaluate the policies in their ability to gain increases in SpO2 while avoiding aggressive ventilator settings which are known to cause ventilator induced lung injuries and other complications. Numerical experiments using MIMIC-III data on the stays of real patients' intensive care unit stays demonstrate that the decision tree policy outperforms the behavior cloning policy and is comparable to state-of-the-art RL policy. Future work concerns better aligning the cost function with medical objectives to generate deeper clinical insights.

Summit - Terrace Suite 2

Sequential Decision Making and Reinforcement Learning Applications in Healthcare

Invited Session

Health Applications Society

Chair: Yonatan Mintz, University of Wisconsin Madison, Madison, WI, United States

1 - Optimal Enrollment TIMES in Early-Stage Clinical Trials

Hanwen Liu, Clemson University, Clemson, SC, United States, Qi Luo, Amin Khademi

Early-stage clinical trials (CTs), including pre-Phase I and Phase I CTs, are crucial for establishing the safety profile of investigational drugs and determining dose-limiting toxicities (DLTs). This research focuses on modeling patients' decision-making processes in early-stage CTs using a Bayesian Optimal Stopping Problem framework, factoring in the efficacy of doses, the evolution of beliefs regarding dose toxicity, and the deterioration in the patient's health. Early-stage CTs adopt a dose-escalation method, where cohorts of patients are sequentially administered increasing doses of the drug until severe DLTs are observed. A control-limit policy for patient enrollment decisions was established with respect to the patient's health state and belief about the dose toxicity. Modeling patients' early-stage CT enrollment decision-making processes lays the groundwork for developing more effective and interpretable strategies for patient recruitment and retention, ultimately contributing to the acceleration of drug development processes.

2 - Data-Driven Patient Flow Optimization

Sogand Soghrati Ghasbeh, University of Michigan, Ann Arbor, MI, United States, Mark P. Van Oyen, Esmaeil Keyvanshokooh, Arlen Dean

Hospitals, as critical infrastructure for population health, face many difficult challenges in converting systems and patient information into evidence-based and personalized decisions. High-quality inpatient hospital care demands the effective and efficient use of hospital beds. However, capacity limitations, high variability across patients, and many human-driven processes make for a challenging environment. Advances in Industrial Engineering (IE) and Applied Operations Research promise to integrate traditional methods with advanced data analytics and decision-making methods to harness the rapidly growing Electronic Health Records (EHR) information to yield unprecedented decision support for this highly complex and essential environment. While Machine Learning and Reinforcement Learning (RL) are evolving rapidly, research from an IE perspective is essential due to the need to capture the dynamics of the system, which feature the complexities of queuing as patients move through a network of service resources, with an emphasis on resource allocation.

By focusing on the patient admission control problem, we aim to reduce adverse events (AEs) while maintaining patient safety and care quality throughout their hospital experience. To optimize a stochastic system model and minimize preventable AEs, the RL method requires a Markov Decision Process (MDP). Moreover, given serious concerns about "safe" policies that restrict online learning's potential, we should explore offline RL algorithms as a conservative approach to mitigate the potential risks associated with online learning. Therefore, to make safe and optimal sequential decisions about patient admissions, we utilize MDP models and a Safe Offline Off-Policy Reinforcement Learning algorithm.

3 - Model Based Learning and Optimization for Personalized Heparin Dosing

Qinyang He, UW-Madison, MADISON, WI, United States, Yonatan Mintz

One of the key challenges in sequential decision making is optimizing systems safely in the case of partial information especially when both states and system dynamics are unknown. For instance, the setting of computing heparin doses for patients fits this paradigm since the concentration of heparin in the patient cannot be measured directly and the rates at which patients metabolize it vary greatly between individuals. To address above challenges in heparin dosing we build a predictive model based on pharmacokinetics parameterized individually by patient. Using this personalized model, we can accurately infer patients' states and predict future therapeutic effects. With this learned information, we propose dosing algorithms that robustly keep patients safe in face of observational errors.

Supply Chain Planning and Execution

Invited Session

The Practice Section of INFORMS

Chair: Chun Ye, Amazon.com, Seattle, WA, United States

Co-Chair: Zhikun Gao, Amazon, Bellevue, WA, United States

1 - Validating Network Planning via Customer Centric Baselines

Qi Chen, Amazon, Bellevue, WA, United States

To align resourcing decisions in a large-scale supply chain network, Sales and Operations Planning generates optimal aggregate flow and capacity plans given customer demand and vendor supply projections. These plans must strike a balance between incentives of disparate business units. We evaluate common baseline-generation approaches for assessing plan and execution quality against instances of a network model. We show that our choice of methodology may lead to conflicting interpretations of plan quality.

2 - Middle Mile Capacity Planning

Ioannis Spantidakis, Amazon, Seattle, WA, United States

Amazon's middle mile network is the backbone of its logistics operations, connecting fulfillment centers to last-mile delivery stations. We explores Amazon's capacity planning strategies for this crucial segment, its integration with demand forecasting, and its online fulfillment optimization routing. We highlight the challenges of managing a vast transportation network and the innovative solutions employed to enhance efficiency and reduce costs without sacrificing delivery speed.

3 - Causal Inference in Transportation Efficiency Estimation

Zhikun Gao, Amazon, Sammamish, WA, United States

Ground transportation plays a crucial role in Amazon's transportation network, for example using Line-Haul (LH) trucks. The modification of network connection and configuration will lead to changes in operation processes, which impacts transportation efficiency as a result. Learning the dependence relationships between operation processes and transportation efficiency helps us to quantify benefits of changing network designs, as well as identify opportunities to further improve operations. This talk introduce a generalized causal inference framework to attribute causal factors of transportation efficiency on operation processes. Through this framework, we can assess the impacts of network re-configurations and explore the potential for further improvement.

4 - Inventory Feasible and Capacity Compliant Facility Assignment Model

Arun Jotshi, Amazon, Seattle, WA, United States, Ayten Turkcan Upasani, Yufei Wang, Kaushik Krishnan

Amazon's fulfillment network is enormous in scale. For US alone there are hundreds of fulfillment warehouses (called fulfillment centers or FCs) located throughout the country where customer orders get fulfillment. The assignment of the orders placed by customers located across the country to the FCs is a critical decision as it generates the origin-destination (OD) flows of shipments which determine transportation cost and delivery speed. In this paper, we present FC Assignment Model (FCAM), a planning system that produces the optimized OD flows to guide the actual order assignment of the fulfillment execution systems. It is formulated as a linear programming problem with the objective is to minimize the total distance of OD flows subject to FC capacity and inventory availability constraints. The key challenge is the enormous product selection (hundreds of millions) which makes modeling individual products intractable. An important innovation of FCAM is the incorporation of inventory bounds at aggregated level without tracking individual products. Our back-testing with historical data shows that the optimized OD flows produced by FCAM are inventory feasible and capacity compliant with significant distance reductions compared with historical actuals without FCAM.

5 - Solving Large Scale Assignment Problems with Decomposition

Ozlem Bilginer, Amazon.com, SEATTLE, WA, United States

Various Amazon outbound execution systems need to allocate orders to paths subject to multiple constraints. The path decision for the orders includes fulfillment center choice, there are many paths out of each eligible fulfillment center, and paths are subject to capacity constraints. As such, these are large scale assignment problems, not easily solvable in their canonical form. In this talk, we present a decomposition algorithm to find primal and dual optimal solutions for one of these large scale linear assignment problems. We discuss the strategies for fast convergence, including problem reformulation and mixed use of various dual update methods.

An Introduction to Decision Diagrams for Optimization

Invited Session

TutORial

Chair: Harish Krishnan, University of British Columbia, Vancouver, BC, Canada

1 - An Introduction to Decision Diagrams for Optimization

Willem-Jan van Hoeve, Carnegie Mellon University, Pittsburgh, PA, United States

This tutorial provides an introduction to the use of decision diagrams for solving discrete optimization problems. A decision diagram is a graphical representation of the solution space, representing decisions sequentially as paths from a root node to a target node. By merging isomorphic subgraphs (or equivalent subproblems), deci sion diagrams can compactly represent an exponential solution space. This ability can reduce solving time and memory requirements potentially by orders of magnitude. That said, exact decision diagrams can still be of exponential size for a given problem, which limits their practical applicability to relatively small instances. However, recent research has introduced a scalable approach by compiling polynomial-sized relaxed and restricted diagrams that yield dual and primal bounds, respectively. These can be combined in an exact search to produce a generic decision diagram-based branch and-bound method. This chapter describes how this approach provides a scalable solution method for state-based dynamic programming models. In addition, the chap ter shows how this approach can be applied to, and embedded in, other computational paradigms including constraint programming, integer programming, and column elim ination. After this chapter, readers will have an understanding of the basic principles of decision diagram-based optimization, an appreciation of how it compares it to other optimization methods, and an understanding of what types of optimization problems are most suitable for this new technology.

Emerging Topics in IS and OM

Invited Session

Information Systems

Chair: Xingyu Fu, University of New South Wales, Sydney, 2113, Australia

Co-Chair: Pin Gao, The Chinese University of Hong Kong, Shenzhen, Shenzhen, N/A

1 - Fishing in the Same Pond: Campaign Interference in Digital Advertising

Francesco Balocco, Vrije Universiteit, Amsterdam, Netherlands, Yixin Lu, Bernd Skiera, Lennart Kraft

Display advertising has evolved into a sophisticated digital supply chain in the past decade. Advertisers increasingly rely on intermediaries known as Demand Side Platforms (DSPs) to streamline the complex tasks of running ad campaigns and purchasing digital ad spaces (impressions) via real-time auctions. DSPs automate the process of targeting and bidding, representing their clients in the digital ad marketplace.
Advertisers running concurrent campaigns for different marketing goals (e.g., brand awareness vs. retargeting) often employ multiple DSPs, each with its unique technology and expertise. While providing access to specialized tools for more effective campaign management, this approach may introduce inefficiencies.
Our research investigates how running campaigns via multiple DSPs undermines advertisers' revenues. Using a dataset of over 1.2 million ad auctions, we show that DSPs working for the same advertisers often inadvertently bid against each other for the same audience, driving up costs and leading to a decrease in the return on investment (ROI) for campaigns.
Based on this evidence, we formulate the optimal campaign combination selection problem in the presence of overlaps. Using actual instances from our ad auction dataset, we analyze the difference between the advertisers' realized revenues and their counterfactual revenue from using the optimal campaign combination. We finally perform computational experiments and approximate the advertisers' optimal campaign revenue using multi-armed bandits.

2 - Licensing and Contracting on the Intellectual Property Contests

Dayu Wu, University of Wisconsin-Madison, Madison, WI, United States

Innovation contests offer a novel and effective method for firms to source intellectual property (IP) from the public. A significant challenge for firms is designing an IP contest that both stimulates creativity and ensures profits. Firms must consider market demand and IP strategies, choosing between upfront and royalty-based licensing contracts to motivate participation and reduce sourcing costs. This study develops a novel contest model to determine optimal IP contest design, focusing on IP strategies and licensing contract decisions. We derive the optimal licensing mechanisms under various scenarios. Our findings indicate that the royalty licensing contract dominates upfront licensing contract as royalty rate increases. Innovators motivated by potential IP monetization exert extra effort to win the royalties licensing contract. However, with a low licensing rate, upfront licensing contracts boost more innovation effort than royalty-based contracts. Furthermore, we explore the effects of collaborative R&D between firms and innovators through IP contest. While reducing R&D costs, collaboration could have negative impacts on product quality, doing harm to the company profits. Our analysis provides insights into collaborative innovation ecosystems and effective IP management, highlighting the balance between fostering innovation and maintaining product standards.

3 - Monetary vs Attention Subsidies on Two-Sided Platforms

Chang Dong, Durham University, Durham, United Kingdom

Facilitating the creation of high-quality content is critical to the success of two-sided platforms. We develop an analytical framework about the equilibrium consequences of two canonical types of subsidy policies in platform governance: providing additional monetary rewards or audience attention to content creators. Cultivating and identifying quality content providers is time-consuming, and these content providers often have limited lifecycles. With a dynamic model, we examine both the short-term and the long-term impacts of the two subsidy policies. Recognizing the intergenerational linkage between new and old content providers has a profound impact on the market equilibrium and the effect of platform governance policies. Our work provides concrete guidelines to help platform managers design subsidy policies to encourage content creation.

1 - An Optimization Framework for Constructing Diversified Portfolios in Market Graphs

Maciej Rysz, Miami University, Oxford, OH, United States

Integration of market graphs with traditional portfolio optimization models is a relatively unexplored area. Existing studies predominantly focus on either portfolio optimization or the construction of market graphs in isolation, with limited exploration of the underlying properties when combining both. This work considers a general risk-reward portfolio optimization model that captures interactions between different assets using a market graph. Focus is put on the interplay between risk measures, graph types, optimal set structures, and portfolio performance. In particular, the model is explored within the context of higher-moment coherent risk measures, correlation and sign market graphs, with the goal of identifying diversified sets of assets that form distance-based independent sets in the underlying graphs. Computational results demonstrate that integrating a graph structure can significantly improve the performance over standard portfolio optimization models and help avoid overfitting. Overall, this study contributes to a deeper understanding of the potential benefits derived from utilizing graph structures in stochastic optimization models.

2 - Global Optimization Approaches to Solving Large Nonlinear Equation Systems: Applications and Techniques

Alexander Semenov, University of Florida, Shalimar, FL, United States, William Trevena, Michael Hirsch, Panayote (Panos) Pardalos

Solving systems of nonlinear equations, even small ones, can be quite challenging. As the size of the systems increases, the complexity of finding all solutions can grow dramatically. This research explores the transformation of such systems into global optimization problems and utilizes efficient algorithms to efficiently find all solutions. The talk includes examples demonstrating the approach on large systems. We experiment with derivative-free optimization algorithms alongside gradient-based algorithms, utilizing automatic differentiation.

3 - The Polarizing Effect of News Playlists on YouTube

Nehir Tanyel, University of Texas at San Antonio, San Antonio, TX, United States

This study delves into the polarization effects observed within news playlists established by prominent channels like Fox and CNN, focusing on contentious topics such as war. Unlike personalized playlists, these curated collections offer a unique lens into the dissemination of polarizing viewpoints by influential media outlets. Through a comprehensive analysis of content composition, viewer engagement, and the amplification of divergent narratives, this research aims to uncover the mechanisms driving polarization within these curated news playlists on YouTube.

4 - Social Media Use and Mental Well-being: The Effect of Motives and Use Behavior

Chinju Paul, Mississippi State University, Starkville, MS, United States

This study delves into the impact of social media usage on depression and mental well-being. While existing literature suggests a link between social media use and heightened depression alongside decreased well-being, some studies propose a positive correlation with well-being. The inconclusive finding warrants an examination of how individuals engage with social media. The literature identifies two main types of use – active use and passive use. Active use involves interacting with content by posting, commenting, or engaging in political causes. Conversely, passive use involves simply scrolling through content without interaction. Our preliminary analysis reveals that active social media use reduces depression levels, whereas passive use exacerbates them. Moreover, different types of active use and passive use result in varied effects. To deepen our understanding, we explore users' motives for engaging with social media and how they align with their usage patterns. We hypothesize that when users' motives align with their behavior, it enhances well-being, irrespective of active or passive engagement. Conversely, misalignment leads to poorer mental well-being and may result in excessive social media usage due to reduced satisfaction. To empirically test these hypotheses, we will conduct surveys and interviews. This research offers both theoretical and practical contributions. By providing comprehensive insights into how social media usage patterns influence mental well-being, it enriches existing literature in the field. Additionally, this study can offer users insights to modify their social media use patterns to better align with their motives and derive benefits from their social media use.

5 - Insecure? How Ephemerality Affects Privacy and Self-Misrepresentation on Online Social Networks: A Moderated Moderation Model

Siwei Jiang, Mississippi State University, Starkville, MS, United States

Online social networks (OSNs) provide users with great opportunities to interact with others while selectively disclosing themselves by building a digital self-image. In privacy literature, privacy concerns have been demonstrated as one of the reasons that cause users to provide fabricated information on OSNs. To reduce users' privacy concerns and facilitate more authentic self-representations, some OSNs introduced an ephemerality feature, which limits the visibility of users' information or content only for a short timeframe. However, psychology scholars show that insecure users especially young teenagers/adults are more prone to use impression management to achieve a desirable self-image on OSNs not only for social connections or support but also for potential social bonds and perceived traits based on their self-deceptive communications. Drawing upon the privacy calculus and self-impression perspective, this study examines the three-way interaction between privacy concerns and the ephemerality feature with users' insecurity states. We hypothesize that the ephemerality feature can effectively reduce users' privacy concerns and then lead to more willingness to disclosure intention, but this moderating effect varies contingent on the types of users' security states. We plan to conduct a survey study to empirically validate the hypotheses. Our study is expected to have both theoretical and practical implications. We contribute to the privacy literature by explaining users' self-disclosure behavior from an insecure emotional perspective and ephemerality of the content. For practitioners, this study indicates that OSNs should reconsider their content-sharing strategies by considering the mental well-being of users to foster a more authentic and transparent communication environment.

Innovations in AI for Optimization and Control

Contributed Session

Chair: Yujie Wang, University of Miami, 8255 SW 72nd Ct, Miami, FL, 33143, United States

1 - Interactive Real-time Decision Support in Digital Control Rooms: An Empirical Study on Generative AI Implementation

Marijn Verschelde, IÉSEG School of Management, Lille, France, Kristof Coussement, Léon Sobrie

In this paper, we explore the use of generative AI to provide customizable, explainable real-time decision support for operational end users who must make split-second decisions under variable time constraints. Our empirical study, conducted within the context of digital railway control room management at Infrabel, addresses the challenges posed by a constant stream of tasks with both expected and unexpected peaks. Traditional visualizations of local and global SHAP (Shapley Additive Explanations) have been found to be too time-consuming to interpret and insufficiently tailored to the specific needs of operators and settings. We evaluate the effectiveness of recent advancements in generative AI in enhancing XAI-based predictive analytics, enabling setting- and operator-specific customization and interactive decision support.

2 - Enterprise-Wide Optimization Using AI-Driven Mathematical Programming

Carlos Paternina-Arboleda, San Diego State University, San Diego, CA, United States, Jesus Velasquez

Mathematical programming (MP) is a cornerstone of optimization across various disciplines. However, formulating effective MP models often requires significant human expertise. This article explores the intersection of generative artificial intelligence (AI) and MP, proposing a novel framework termed Generative Mathematical Programming Artificial Intelligence (GMP-AI). GMP-AI leverages AI's ability to learn patterns from data to automate MP model generation. The framework empowers the AI to learn the relationships between problem data and the corresponding model structure. This paves the way for GMP-AI to generate new MP models for unseen optimization problems within the learned domain. The article discusses the potential applications of GMP-AI in various fields and concludes by outlining promising avenues for future research in this emerging area. Although our work has made great advancement in automating the process of building large-scale mathematical models, based on the libraries created, there is still a lot of potential for growth in this promising field.

3 - Asymptotic Behavior of Adversarial Training Estimator Under L_\Infty-Perturbation

Yiling Xie, Georgia Tech, ATLANTA, GA, United States, Xiaoming Huo

Adversarial training has been proposed to hedge against adversarial attacks in machine learning and statistical models. This paper focuses on adversarial training under ℓ_∞-perturbation, which has recently attracted much research attention. The asymptotic behavior of the adversarial training estimator is investigated in the generalized linear model. The results imply that the limiting distribution of the adversarial training estimator under ℓ_∞-perturbation could put a positive probability mass at 0 when the true parameter is 0, providing a theoretical guarantee of the associated sparsity-recovery ability. Alternatively, a two-step procedure is proposed---adaptive adversarial training, which could further improve the performance of adversarial training under ℓ_∞ perturbation. Specifically, the proposed procedure could achieve asymptotic unbiasedness and variable-selection consistency. Numerical experiments are conducted to show the sparsity-recovery ability of adversarial training under ℓ_∞-perturbation and to compare the empirical performance between classic adversarial training and adaptive adversarial training.

4 - A Novel Heterogeneous Recurrence Network Analysis for Spatiotemporal Data

Yujie Wang, University of Miami, Coral Gables, FL, United States, Cheng-Bang Chen

Recent advancements in recurrence analysis have significantly enhanced our understanding of dynamical systems, uncovering complex, non-linear, and non-stationary properties in various fields such as manufacturing, healthcare, and social sciences. Despite these advances, there is a notable gap in applying recurrence methods to spatiotemporal data, which is prevalent in nature and contains diverse patterns worth exploring. To address this, we propose a novel methodology: heterogeneous recurrence network analysis for spatiotemporal data. This approach processes data chronologically while preserving spatial information, thereby maximizing data utility. We validate our methodology by analyzing the high dimensional EEG signals to distinguish human emotions over time. This innovative application not only aids in mental health diagnosis but also provides deeper insights into spatiotemporal dynamics.

Regency - 606

Strategies in ESG and Contractual Decisions

Contributed Session

Chair: WENTING LI, Arizona State University, Tempe, AZ, 85044-1746, United States

1 - Optimal Contract Selection Strategies Under Three Different Structures

Qing Zhu, Nanjing University of Science and Technology, nanjing, China, People's Republic of, Yudong Wang, Stephen Disney, Wei Xing

We explore optimal contract choice under monopoly, retailer competition, and manufacturer competition structures. The impact of interest rates and the substitution rate between two products on manufacturers' and retailers' profits is also considered. We also focus on the similarities and differences between the manufacturers and the retailers under Bertrand and Cournot competition. We identify the contracts the manufacturers wish to adopt, the contracts the retailers prefer manufacturers to choose, and whether there are differences in the reasons for contract selection. Our model employs a two-stage Stackelberg game. The research findings indicate that in the monopoly case, with retailers engaging in either Bertrand and Cournot competition, the volatility of spot market price affects the manufacturer's contract choice and the retailers' contract preferences in the same manner. We found that under manufacturer competition, whether in Bertrand or Cournot games, the manufacturer's contract choices and equilibrium strategies are the same. However, in this structure, the retailers' preferences for the type of contract chosen by manufacturers may vary depending on the magnitude of market demand price volatility. Furthermore, the study concludes that under the two game modes of manufacturer and retailer competition, both manufacturer and retailer profits decrease with an increase in the substitutability between the two products, and manufacturer profits decrease with interest rate increases.

2 - ESG Data Imputation and Greenwashing

Giulia Crippa, Princeton University, Princeton, NJ, United States

In recent years, there has been a notable surge of Environmental, Social, and Governance (ESG) investing. This paper provides a simple and comprehensive tool to tackle the issue of missing ESG data. Firstly, it allows to shed light on the failure of ESG ratings due to data sparsity. Exploiting machine learning techniques, we find that the most significant metrics are promises, targets and incentives, rather than realized variables. Then, data incompleteness is addressed, which affects about 50% of the overall dataset. Via a new methodology, imputation accuracy is improved with respect to traditional median-driven techniques. Lastly, exploiting the newly imputed data, a quantitative dimension of greenwashing is introduced. We show that when rating agencies do not efficiently impute missing metrics, ESG scores carry a quantitative bias that should be accounted by market players.

3 - Relative vs. Absolute Volume-Based Export Restrictions: Choice, Design, and Effectiveness

Lucy Chen, National University of Singapore, Singapore, Singapore, Srinagesh Gavirneni, Aditya Vedantam, Shuguang Zhang

We study a firm’s production and export decisions when facing export restrictions imposed by the government, who aims to maximize the social welfare. We investigate how different export restrictions affect the firm’s decisions and profitability as well as the social welfare.

4 - A Procurement Advantage in Disruptive Times: New Perspectives on ESG Strategy and Firm Performance

Wenting Li, Arizona State University, Tempe, AZ, United States, Yimin Wang

This study investigates whether elevated environmental, social, and governance (ESG) practices in the global supply chain confer firm resilience during disruptions, and, if so, the underlying mechanisms. Drawing on the COVID-19 pandemic as a natural experiment, we define a firm's resilience as its relatively superior financial performance during the pandemic. To isolate the causal effect of ESG practices on a firm's resilience, we employ an instrumental variable estimation approach, exploiting exogenous variation in ESG practices driven by firms' exposure to political orientations. The results reveal that increased ESG practices strengthen a firm's resilience during disruptions: a 1% increase in ESG practice scores leads to a 0.215% increase in firms' return on assets. We analyze the mechanisms driving this resilience effect and show that improved ESG practices are associated with reduced purchasing costs and higher profitability amid disruptions. Through a series of mechanism tests exploiting heterogeneity of stakeholder resources, we provide robust evidence that ESG enhances operational congruency with suppliers, which becomes critical in securing a procurement advantage during severe external constraints. Contrary to popular belief, there is little evidence that the ESG improves price premiums during the disruption. Therefore, strengthening operational alignment with suppliers is more critical than fostering customer loyalty with ESG labels, highlighting the primacy of ESG-enabled upstream stakeholder collaborations. Managerially, this research quantifies the economic rationale for ESG practices, offering managers empirical evidence on the imperative to prioritize specific stakeholder alignments as opposed to broad, vague ESG practices that may harm firm performance.

SpORts II: SpORts Betting and Social Impact

Invited Session

spORts

Chair: Jay Simon, American University, Washington, DC, United States

1 - Inefficiencies In the Betting Market for Popular Events? Evidence from the Ncaa Men&Rsquo;S Basketball Tournament

Dan Hickman, University of Idaho, Moscow, ID, United States

The NCAA men’s basketball tournament, commonly referred to as March Madness, generates a significant amount of betting activity. The rise in legal access to sports gambling in the United States, along with the popularity of the event mean that a substantial number of those taking part in the market may not be regular market participants. Is it possible for an informed participant to exploit potential biases in the market? This study analyzes outcomes from the past 30 years to determine whether factors such as regular season performance, travel distances, game time, recency bias or others lead to inefficiencies in the market.

2 - Betting Line Movement and Inefficiencies in Four Major spORts

Jay Simon, American University, Washington, DC, United States

This work explores real-time betting line movement in four major sports. Particular attention is given to how both new and previously observed inefficiencies evolve over the duration of the betting window for each game. While sportsbooks' prices are generally reliable, they are not perfect, and several inefficiencies arise.

3 - Online spORts Gambling and Individual Wellbeing

Mike Gordon, Virginia Tech, Blacksburg, VA, United States

While legalization has led to an explosion in the popularity of online sports gambling, research has not evaluated the impact of the change in access to sports gambling on societal welfare. We evaluate the impact of the legalization and digitization of online gambling on mental health, financial, and crime outcomes. We look to understand how nascent avenues for gambling affect consumers at large. We additionally look to address potential disparities in the population and how they affect this behavior.

4 - Carbon Footprint Impact of NCAA Conference Realignment

Sia Sheguri, Arizona State University, Tempe, AZ, United States, Jiayi Hong, Ross Maciejewski, Ron Askin

With the recent realignments in the National Collegiate Athletic Association's Power Five conferences, there has been a surge in travel distances between games, thereby elevating the carbon footprint dramatically. In this work, we investigate the impact of conference realignment on carbon footprint using team travel for football games as a proportional surrogate for impact. Using the geographic location of each team and typical travel method of air for trips exceeding 200 miles (bus for shorter trips), along with historical and proposed schedules, the carbon footprint produced by Power Five team schedules is computed before and after recent realignments. A model is developed to optimally divide each conference into divisions and the potential savings of using divisions as opposed to random within conference scheduling is shown. We believe that these strategic sub-divisions could be a step towards a greener collegiate sports community and mitigate the impact of realignment. Finally, for comparison, a model is developed to allocate the set of Power Five teams into an optimal set of conferences for minimizing carbon footprint. The model can be extended to include factors such as desired population coverage or other economic constraints to ensure recruiting and exposure goals.

Optimization and Machine Learning in Power Systems

Invited Session

ENRE: Electricity

Chair: Minseok Ryu, Arizona State University, Tempe, AZ, United States

1 - Physics-Informed Heterogeneous Graph Neural Networks for DC Blocker Placement

Hongwei Jin, Argonne National Laboratory, Lemont, IL, United States

The threat of geomagnetic disturbances (GMDs) to the reliable operation of the bulk energy system has spurred the development of effective strategies for mitigating their impacts. One such approach involves placing transformer neutral blocking devices, which interrupt the path of geomagnetically induced currents (GICs) to limit their impact. The high cost of these devices and the sparsity of transformers that experience high GICs during GMD events, however, calls for a sparse placement strategy that involves high computational cost. To address this challenge, we developed a physics-informed heterogeneous graph neural network (PIHGNN) for solving the graph-based dc-blocker placement problem. Our approach combines a heterogeneous graph neural network (HGNN) with a physics-informed neural network (PINN) to capture the diverse types of nodes and edges in ac/dc networks and incorporates the physical laws of the power grid. We train the PIHGNN model using a surrogate power flow model and validate it using case studies. Results demonstrate that PIHGNN can effectively and efficiently support the deployment of GIC dc-current blockers, ensuring the continued supply of electricity to meet societal demands. Our approach has the potential to contribute to the development of more reliable and resilient power grids capable of withstanding the growing threat that GMDs pose.

2 - A Bidding Strategy Algorithm for Distributed Energy Resource (DERs) Aggregators: Participation in Day-ahead and Real-time Energy and Ancillary Markets

Sara Ostovar, Arizona State University, Tempe, AZ, United States, Mojdeh Hedman

Federal Energy Regulatory Commission (FERC) Order No. 2222 paved the way for Distributed Energy Resource (DERs) to participate in the wholesale market via aggregations to meet regulatory requirements. However, it is necessary to develop bidding strategies unique to DER aggregators due to the uncertainty and low operational cost. Multiple work in literature investigate the bidding strategy of DER Aggregators, considering the risk of failing obligations which pose financial risks to the aggregator.
This work proposes a bidding strategy for a DER aggregator whose resource mix comprises Photovoltaic (PV) units and Energy Storage Resources (ESRs) participating in the day ahead and real-time energy and ancillary service market. This work covers the day-ahead model with a vision of real-time as well as a separate real-time bid generation module. Regulation-up is considered concerning the participation of DERs in provision of ancillary services. The framework uses a scenario-based modeling approach for market price and PV output power uncertainty. The model produces price-quantity offer curves for the day-ahead and real-time energy and ancillary service market.

3 - Grid-Aware on-Route Fast-Charging Infrastructure Planning for Battery Electric Bus with Equity Considerations: a Case Study in South King County

Xinyi Zhao, University of Washington, Seattle, WA, United States, Chaoyue Zhao, Grace Jia

The transition from traditional bus fleets to zero-emission ones necessitates the development of effective planning models for battery electric bus (BEB) charging infrastructure. On-route fast charging stations, distinct from on-base charging stations, present unique challenges related to safe operation and power supply capacity, making it difficult to control grid operational costs. This paper establishes a novel framework that integrates the bus route network and power network, which leverages the inter-dependency between both networks to optimize the planning outcomes of on-route BEB charging stations in South King County. The problem is formulated as a mixed-integer second-order cone programming model, aiming to minimize the overall planning cost, which includes investments in charging equipment, power facility, and grid operation. Furthermore, fairness measurements are incorporated into the planning process, allowing for the consideration of both horizontal transit equity and vertical transit equity based on different zone merging criteria within the county's existing census tracts. The results of this planning model offer valuable insights into achieving both economic efficiency and social justice in the design of on-route charging facilities for BEBs in South King County.

4 - Scalable Algorithms for Mitigating Impacts of Geomagnetic Disturbances on Electric Grids

Joshua Clugston, Arizona State University, Tempe, AZ, United States, Minseok Ryu

Space weather introduces geomagnetically induced currents (GICs) into the electrical grid, potentially disturbing grid operation and causing damage to grid infrastructure. The risks imposed by GICs can be reduced by the appropriate placement of GIC blocking devices. However, optimal placement of such devices typically leads to solving a challenging mixed-integer nonlinear program (MINLP). To address the computational challenges posed, we therefore propose an alternating direction method of multipliers (ADMM) based heuristic algorithm, developed by exploiting the structure of the blocker placement problem. We demonstrate on the ACTIVSg2000 synthetic grid test case that our heuristic algorithm produces high-quality solutions for moderately sized blocker placement problems without expending substantial computational resources.

5 - Electricity price forecasting in a power network using GNN-based encoder-decoder architecture

Krishna Rijal, University of South Florida, Tampa, FL, United States, Nicolas Bustos, Tapas Das

Electricity price forecasting (EPF) is a critical function in the electricity market due to its potential impact on resource planning and allocation, cost management, and profit maximization. The inherent complexity arising from fluctuating supply from diverse sources and variable demand patterns presents a challenge in accurate electricity price prediction. In this study, we propose an approach leveraging graph neural networks (GNNs) for EPF integrating factors such as supply and demand variations, network power flow, and other exogenous variables. The graph representation considers the demand, generation, weather information, and fuel costs as the node attributes while the power flow is considered as the edge attribute. The model architecture also considers a self-supervised learning mechanism designed to detect price spikes, which is likely to enhance the accuracy of our price forecasts.

Data Assimilation for Simulation Optimization

Invited Session

Data Mining

Chair: Runsang Liu, The Pennsylvania State University, University Park, PA, United States

Co-Chair: Hui Yang, Pennsylvania State University, University Park, PA, United States

1 - Recurrence Network Modeling for Cardiac Digital Twin

Runsang Liu, The Pennsylvania State University, University Park, PA, United States

The paradigm shift from population-based decision-making towards precision medicine has led to a plethora of imaging data of the heart. While most of these accumulated data are underutilized, there is a need to develop effective representations of heart geometry and further enable the integration of different types of clinical data to dissect disease heterogeneity and assist intervention planning. In this paper, we present a new recurrence network representation of the heart. Each point in the heart geometry is treated as a vertex, and the edges are formed based on the spatial proximity of vertices. By simulating the network as a physical system, the network self-organizes into a steady topology by minimizing system energy. Experimental results show the effectiveness of the recurrence network model of heart by reconstructing both the external and internal structures of the heart.

2 - Multi-Source Data and Knowledge Fusion via Deep Learning for Dynamical Systems: Applications to Spatiotemporal Cardiac Modeling

Bing Yao, The University of Tennessee Knoxville, Knoxville, TN, United States

Advanced sensing and imaging provide unprecedented opportunities to collect data from diverse sources for increasing information visibility in spatiotemporal dynamical systems. Furthermore, the fundamental physics of the dynamical system is commonly elucidated through a set of partial differential equations (PDEs), which plays a critical role in delineating the manner in which the sensing signals can be modeled. Reliable predictive modeling of such spatiotemporal dynamical systems calls upon the effective fusion of fundamental physics knowledge and multi-source sensing data. This paper proposes a multi-source data and knowledge fusion framework via deep learning for dynamical systems with applications to spatiotemporal cardiac modeling. This framework not only achieves effective data fusion through capturing the physics-based information flow between different domains, but also incorporates the geometric information of a 3D system through a graph Laplacian for robust spatiotemporal predictive modeling. We implement the proposed framework to model cardiac electrodynamics under both healthy and diseased heart conditions. Numerical experiments demonstrate the superior performance of our framework compared with traditional approaches that lack the capability for effective data fusion or geometric information incorporation.

3 - Small Data and Sparse Bayesian Learning for Sequential Inference of Network Connectivity

Jinming Wan, Binghamton University, Vestal, NY, United States

While significant efforts have been attempted in the design, control, and optimization of complex networks, most existing works assume the network structure is known or readily available. However, the network topology can be radically recast after an adversarial attack and may remain unknown for subsequent analysis. In this work, we propose a novel Bayesian sequential learning approach to reconstruct network connectivity adaptively: A sparse Spike and Slab prior is placed on connectivity for all edges, and the connectivity learned from reconstructed nodes will be used to select the next node and update the prior knowledge. Central to our approach is that most realistic networks are sparse, in that the connectivity degree of each node is much smaller compared to the number of nodes in the network. Sequential selection of the most informative nodes is realized via the between-node expected improvement. We corroborate this sequential Bayesian approach in connectivity recovery for the IEEE-118 power grid system. Results indicate that only a fraction (~50%) of the nodes need to be interrogated to reveal the network topology.

4 - Digital Twinning and Optimization of Manufacturing Process Flows

Hankang Lee, The Pennsylvania State University, University Park, PA, United States, Hui Yang

The new wave of Industry 4.0 is transforming manufacturing into data-rich environments. This provides an unprecedented opportunity to feed large amounts of sensing data collected from the physical factory into the construction of digital twin (DT) in cyber-space. Despite this potential, there has been limited exploration of how DT technology can enhance the efficiency and autonomy of small and medium-sized manufacturing enterprises. Therefore, there is an urgent need to exploit the full potential of data analytics and simulation-enabled DTs for advanced manufacturing. Hence, this study presents the design and development of DT models for simulation optimization of manufacturing process flows. First, we develop a multi-agent simulation model describing nonlinear and stochastic dynamics among a network of interactive manufacturing things, including machines, automated guided vehicles (AGVs), queues, and jobs. Second, we propose a statistical metamodeling approach to design sequential computer experiments aimed at optimizing AGV utilization under uncertainty. Third, we construct two new graph models—job flow graph and AGV traveling graph—to monitor and analyze the real-time performance of manufacturing jobshops. The effectiveness of the proposed simulation-enabled DT approach is assessed through experimental studies. Results show that the proposed methodology effectively transforms conventional manufacturing jobshops into novel DT-enabled smart factories. The sequential design of experiments significantly reduces the computational overhead of expensive simulations while efficiently scheduling AGVs to achieve cost-effective production throughput. This research is strongly promised to help manufacturers fully utilize big data and DT technology to gain competitive advantages in the global marketplace.

Advancements in Medical Data Analysis and Intervention

Contributed Session

Chair: Gunsu Dagistanli, N/A

1 - Enhanced Laryngeal Cancer Screening Using Deep Learning: Integrating Phoneme Analysis, Diverse Sentence Structures, and Patient Data

Yong Oh Lee, Hongik University, Seoul, Korea, Republic of

Symptoms of laryngeal cancer manifest primarily through voice changes, and diagnosis typically relies on laryngoscopy. This process lacks objective indicators for voice changes, making early detection difficult. Recent advances in deep learning have opened up new possibilities for voice-based laryngeal cancer screening, but its clinical application is still limited due to its relatively low accuracy.
In this presentation, we propose a multi-faceted approach to address these issues and improve screening performance. First, we adopt a phoneme-based detection approach using the /a:/ phoneme and compare two feature extraction methods: Mel-frequency correlation coefficient (MFCC) and octave-frequency correlation coefficient (OFCC). The results show that OFCC achieves higher performance than MFCC in laryngeal cancer detection. Second, we extend our analysis to include different sentence forms without relying solely on the /a:/ phoneme. This allows us to capture a wider range of vocalization characteristics affected by laryngeal cancer, providing a more

comprehensive voice screening. Third, we integrate patient information such as age, gender, and medical history with the results of voice signal analysis using convolutional neural network (CNN) models. The fusion of these data significantly improves the accuracy of the screening tool.
Experimental results show that this integrated approach can accurately distinguish laryngeal cancer more than 90% of the time.

2 - Binary Gaussian Copula Synthesis: Pioneering Data Augmentation for Early Dialysis Intervention in CKD Patients

Hamed Khosravi, West Virginia University, Morgantown, WV, United States, Srinjoy Das, Mohammad Abdullah Al-Mamun, Imtiaz Ahmed

The Center for Disease Control estimates that over 37 million US adults have chronic kidney disease (CKD), with 90% unaware of their condition due to symptomless early stages. This disease severely affects life quality, particularly as it progresses to requiring dialysis. Early dialysis prediction is crucial for improving patient outcomes and aiding healthcare providers in timely decision-making. However, developing an effective machine learning (ML)-based Clinical Decision Support System (CDSS) for such early prediction is challenging due to data imbalance—there are significantly fewer dialysis than non-dialysis CKD patients, which hampers the accuracy of ML models.

To tackle this, we introduce a novel approach named Binary Gaussian Copula Synthesis (BGCS), specifically designed for binary medical datasets. BGCS excels at generating synthetic data that preserves the original distribution, enhancing the detection of potential dialysis patients. Our results show that BGCS outperforms traditional methods, improving dialysis prediction across various ML models. For example, using a Random Forest model, BGCS achieved a 72% improvement over state-of-the-art augmentation methods, demonstrating significant enhancements even compared to situations without augmentation. Additionally, we developed an ML-based CDSS using decision tree models, favored for their interpretability in healthcare. This system is engineered to assist clinicians in proactive decision-making and effective treatment planning for CKD patients likely needing dialysis soon. Through detailed feature analysis and careful data preparation, our CDSS delivers accurate, actionable predictions, serving as a vital tool in CKD management and treatment.

3 - Matching mechanism and queuing model in organ transplantation

Nani Zhou, Shanghai Jiao Tong University, Shanghai, China, People's Republic of

Organ transplantation is the most effective treatment for many end-stage cancers. In the case of kidney transplantation, for example, most patients with end-stage renal disease wait in line on the deceased donor waiting list. ABO blood group compatibility is one of the main indicators of the match between a cadaveric kidney and a patient. The O blood group is the universal donor and the AB blood group is the universal recipient. Since the demand for kidneys is much higher than the supply, how to equitably distribute the limited kidney resources to individual patients is an urgent issue that needs to be improved. In the United States, for example, the proportion of blood groups O and A in the population is about 45% and 40%, and the corresponding proportions of blood groups in patients with end-stage renal disease are about 54% and 27%. As O kidneys are available to A patients, the probability of O patients receiving a kidney decreases, the average waiting time increases, and the dropout rate increases (patient deaths). The difficulty of the problem lies in how to measure the fairness of the queuing system and how to carve out the entire stochastic system. When the changes in the state of the system are sliced finely enough by time, we approximate this queuing process as a flow model and explore how to construct fairer kidney matching rules.

4 - Chemotherapy Appointment Scheduling at Hacettepe Oncology Hospital

Gunsu Dagistanli, Middle East Technical University, Ankara, Turkey, Meral Azizoglu

As the demand for chemotherapy treatment rises, efficient planning becomes critical for oncology clinics and hospitals. The first stage of planning, involves allocating patients to treatment days within the constraints of their treatment plans and hospital schedules. The second stage involves preparing daily patient and nurse schedules while adhering to chair limitations and maximizing patient satisfaction.

In this study we address the second stage problem, known as Chemotherapy Appointment Scheduling (CAS) problem, based on our observations at Hacettepe Oncology Hospital in Ankara. We present a deterministic Mixed-Integer Linear Programming (MILP) model with continuous appointment times for various defined single criterion or multi criteria objectives. The results of our computational experiment reveal that our model can handle up to problem instances with 10 patients, 3 nurses and 3 chairs. We also extend the problem to include infusion duration related stochasticity and propose a two-stage Stochastic Mixed Integer Programming (SMIP) model for its solution.

Market Design, Analysis, and Optimziation of Zero-carbon Electricity Market

Invited Session

ENRE: Energy-Climate

Chair: Dongwei Zhao, Argonne National Laboratory, Westmont, United States

1 - Assessing Austria's 2040 Energy Storage Requirements

Robert Gaugl, Institute of Electricity Economics and Energy Innovation/Graz University of Technology, Graz, Austria, Sonja Wogrin

As Austrian decarbonization initiatives emphasize enhanced electrification, there is a notable lack of quantitative estimates/goals regarding necessary storage capacities. In this talk, we examine the expected need for short-, medium-, and long-term energy storage applications in the Austrian power system of 2040. We use a European Net-Transfer-Capacity model, featuring a single node per country, while adopting a finer spatial resolution for Austria. Multiple sensitivity analyses explore the impacts of different weather years, import/export capacities and costs. The study's findings underscore two main points: the pressing need for expanded storage capacity and the significant impact of allowing renewable energy curtailment on storage requirements.

2 - Evaluating Robust Technology Investment Portfolios to Achieve Zero-Carbon Power Systems

Shantanu Chakraborty, Massachusetts Institute of Technology, Cambridge, MA, United States, Audun Botterud, Jessika Trancik

The transition to low-carbon power systems necessitates substantial integration of weather-driven energy resources, such as wind and solar power. To ensure reliable supply of power over time and space, a portfolio of supply-side options and transmission infrastructure is required. While multiple technologies can be considered to provide these capabilities, there is a lack of comprehensive investigation into their trade-offs and complementarities, particularly under parametric uncertainties such as cost assumptions. This research aims to address this gap, offering insights to help identify robust, high-performing technology portfolios that can support future zero-carbon power systems.

This study employs a comparative approach using the Zero-emissions Electricity system Planning with HourlY operational Resolution (ZEPHYR), Sustainable Energy Systems (SES), and GenX models to analyze the roles of energy storage, transmission, demand response, and power generation at national, regional, and local scales. Additionally, we explore parametric uncertainties related to technology cost evolution and potential constraints on transmission infrastructure expansion. We investigate how the optimal deployment of power supply-side options depends on resource availability factors, the ability to expand transmission infrastructure, and the power and energy capacity cost evolution of energy storage. By synthesizing the differences across models, the study identifies favorable technology portfolios while accounting for uncertainties to provide a comprehensive framework that is aimed at guiding investments and policy decisions towards a zero-carbon power system for the US.

3 - Incentivizing long-term low-carbon power system resource adequacy under uncertainty: Accouting for the impact of weather information and extreme events

Shen Wang, Massachusetts Institute of Technology, Catonsville, MD, United States

To address global climate impacts, the electric power system is facing the challenges of achieving grid decarbonization while ensuring reliable power supplies. The transition toward clean renewable technologies, notably wind and solar which are characterized by uncertainty of power generation, could raise electricity supply reliability issues as they may not reliably dispatch electricity when needed. Furthermore, it is also argued that just penalizing outages of large fossil fuel power plants by conventional capacity derating is insufficient to fully account for the risks they introduce, as these plants may experience lengthier periods of outages and exhibit correlated vulnerabilities to extreme weather (i.e., winter blackouts in Texas and heatwave blackouts in California). The capacity accreditation mechanisms that lie at the heart of many present designs of capacity markets may not effectively promote efficient long-term investments, due to weak linkages of planning elements and operational uncertainties driven by weather information. Therefore, it is essential to improve the traditional deterministic planning and resource accreditation methods to capture the impacts of evolving weather-driven extremes on power systems. In this paper, we aim to address these issues through the following research questions below: 1) How can we incorporate weather-informed uncertainty in generation expansion planning, utilizing techniques such as stochastic or robust optimization? 2) Does considering uncertainty in renewable availability and correlated thermal power shutdowns significantly enhance the reliability and cost-effectiveness of resource plans? 3) What capacity credit definitions, informed by weather data, can accurately assess resource adequacy and be the basis of efficient incentives?

4 - 2032 miniWECC: Market Models for Zero Marginal Cost Resources

Allison Campbell, Pacific Northwest National Laboratory, Richland, WA, United States

With increased penetration of inverter-based renewable generation, next-generation power market models will need to evolve to account for the physics and economics of these units. This will require incorporating two new components to facilitate seamless commitment and dispatch of variable renewable generation while supporting system stability: responsiveness to power electronics control setpoints, and adaptation to zero marginal fuel costs. Development of new market model formulations that are responsive to these two conditions requires a testbed system that is both representative of real-world topologies and lightweight enough to facilitate rapid prototyping, but current market model test cases are either purely synthetic or too detailed. To fill this gap, PNNL is developing a testbed that integrates the miniWECC 240 bus power flow case within a new miniWECC market dataset. This talk will present the new 2032 miniWECC market dataset, which was augmented to reflect the capacity additions of the 2032 WECC Anchor Dataset, under the framework of the needs of future market models.

ENRE: Environment and Sustainability

Chair: Sidi Deng, University of Michigan, Ann Arbor, MI, 48108-2918, United States

1 - A Dynamic Material Flow Simulation Model for Risk-Informed Decision-Making in Decarbonizing Aluminum Manufacturing

Sidi Deng, University of Michigan, Ann Arbor, MI, United States, Daniel Cooper, John Sutherland

Aluminum is the world's second most consumed metal, and its production contributes substantially to global greenhouse gas (GHG) emissions. When formulating decarbonization strategies, it is imperative to ensure their coherence and alignment with existing industrial practices and standards. To support risk-informed decision policymaking in decarbonizing aluminum manufacturing, this study develops a dynamic system model that simulates global aluminum flows and computes their embedded GHG emissions. A baseline scenario is devised to reflect the current business and operation landscape, and three decarbonization strategies are proposed. Deterministic simulation is performed to generate dynamic material flows and performance metrics. Monte Carlo simulation is then implemented to evaluate the robustness of the system's performance under demand uncertainties. The results reveal that material efficiency and post-consumer scrap recycling have profound carbon performance implications. Informed by simulation outputs, macro decarbonization guidelines are formulated for various criteria. The object-oriented programming framework that underlies the dynamic MFA may be integrated with network analysis, agent-based simulation, and geospatial interfaces, which may lay the foundation for modeling more fine-grained material flows and supply chain structures.

2 - Digital Product Passports in the U.S.

Kelsea Schumacher, NIST, Gaithersburg, MD, United States, Noah Last, KC Morris

Businesses and policymakers are working to transition away from a linear—take, make, waste—economy into a circular economy (CE) model in which materials are kept in the economy for as long as possible through value-retention strategies like extended use, reuse, and recycling. However, this transition requires a system that shares product lifecycle data to support these value-retention strategies. A Digital Product Passport (DPP) has been proposed, and is being mandated for select products in Europe, as a mechanism to support such data sharing and drive circularity. The DPP concept relies on unique identifiers and decentralized ledger systems to provide extensive data throughout a product's lifecycle in a digital format that is both secure and accessible to some number of parties or stakeholders within the supply chain. Authorized stakeholders would then have access to select data, allowing for informed decision-making based on the product's history, content, or format. DPPs could support verifiable track and trace of materials as well as associated market surveillance. In this presentation, we will discuss the potential role and feasibility of using DPPs in the U.S., highlighting two use cases: batteries and textiles. We will discuss barriers facing the development and adoption of DPPs broadly, specific challenges and opportunities that may exist in the U.S., and preliminary work on the standards and frameworks required to ensure confidence in the quality and reliability of any information contained in them.

3 - Benchmarking Industrial Symbiosis Development using Network Analysis

Abheek Chatterjee, University of Maryland, College Park, MD, United States, Oren Minsk, Matthew Triebe, Buddhika Hapuwatte, Daniel Kietzer, Sushma Kittali-Weidner, KC Morris, Nehika Mathur

Industrial Symbiosis (IS) is the use of resource exchange partnerships between co-located firms to reduce raw material use, emissions, and waste generation, while promoting economic growth. Successful IS efforts contribute towards the Circular Economy transition. However, most IS projects fail in the early stages and do not reap the full sustainability benefits of IS. A significant reason for the failure of early-stage IS projects is the lack of knowledge regarding the strategic organization of IS networks. Quantifying IS network organization and operational characteristics and benchmarking IS development can address this challenge and guide decisions to advance newer IS networks by comparison to the organizational and operational characteristics of mature IS networks. This investigation tests multiple Ecological Network Analysis (ENA) and Social Network Analysis (SNA) metrics using three real-world IS case studies, as potential IS benchmarking tools. The results of the investigation show that ENA and SNA metrics can be used to compare IS networks and identify differences in the following characteristics: Partnership prevalence, producer-consumer relationships, linkage distribution, resource utilization, effect of indirect firm relationships, network cohesion, and network centralization. The values of the multiple network analysis metrics are found to be aligned with the development time of the IS networks and the qualitative markers of IS development stages as identified in the literature. This investigation demonstrates that network analysis of IS projects only requires anonymized and non-proprietary data, and identifies data-collection and modeling standards needed to develop an IS benchmarking framework using network analysis.

4 - The role of material scarcity in clean energy transition: diffusion control and circularity

Emre Nadar, Bilkent University, Ankara, Turkey, Atalay Atasu, Nilsu Uzunlar

The material scarcity may act as an important impediment to clean energy transition. We consider the problem of maximizing renewable energy generation over time to achieve the global climate goals under material scarcity. We model the market adoption of renewable technologies through a Bass diffusion curve and the decision maker's control over the diffusion curve through dynamic production volume choices. We explore novel trade-offs between renewable energy efficiency improvements, renewable technology diffusion growth and replacements, and circularity aimed at mitigating the material-scarcity issue. We identify conditions where delaying renewable technology adoption helps improve renewable energy generation in the long run. We also evaluate how the infrastructural limits to circularity affect the value of managing the diffusion process and to what extent circularity and diffusion control are complements. Our results show the importance of properly accounting for the diffusion process in clean energy transition.

5 - Using Reinforcement Learning to Manage Supply-Demand Balance in Remanufacturing

Abhijit Gosavi, Missouri University of Science and Technology, Rolla, MO, United States, Jiaqiao Hu

In this research, we propose a new reinforcement learning (RL) algorithm rooted in the **actor-critic** framework for approximately solving continuous state/action Markov decision processes. The algorithm uses a Q-function for the critic, which is in contrast to the usual value

function of dynamic programming used in many actor-critics. In this talk, we focus on a discretized version of this RL algorithm that uses exemplars or representative state-action pairs. This version is suitable for a tabular setting, and the algorithm is referred to as the *T*abular *E*xemplar *A*pproximation (*TEA*) version of the actor critic. In many remanufacturing firms, a key objective is to match the supply and demand imbalance commonly experienced with the so-called *cores* or used products. Suppliers of cores are in high demand, but their availability is limited. As a result, suppliers who deliver at more regular and reliable rates tend to be more expensive, while the more erratic suppliers are cheaper. Simultaneously, remanufacturing firms experience variability in their own customer base, and hence demand for their own products can fluctuate significantly. Therefore, unless the supplier is selected judiciously, firms can witness shortages in their finished-product inventory, leading to penalties from customers. The RL algorithm can streamline the supplier selection process, thereby improving efficiencies for the firm. Numerical results are presented to demonstrate the usefulness of the RL algorithm.

Energy Systems Modeling and Optimization I: Policy-Enabling Models in the Energy Sector

Invited Session

ENRE: Other Energy

Chair: Afzal Siddiqui, Stockholm University, Kista, Sweden

1 - Treading Water on a Cloudy Day: Utility Rate-Making in the Presence of Prosumers

Yihsu Chen, University of California, Santa Cruz, Santa Cruz, CA, United States

PUCs (Public Utility Commissions) in some states in the U.S. face daunting challenges in making equitable and efficient retail rates while adequately recovering utilities' fixed costs given a growing amount of DER (distributed energy resources) dominates the grid. We examine the trade-offs among energy equity, economic efficiency, and utility cost recovery in retail ratemaking by formulating the problem as a two-stage stochastic problem. A conditional-value-at-risk approach is implemented to account for the PUC's attitude toward recovering utilities' fixed costs. We demonstrate the (im)possibility of devising a retail rate that is equitable while also minimizing the risk of unrecovered fixed costs at the intangible expense of efficiency. Our work, thus, highlights the need to strike a delicate balance among those factors in today's ratemaking.

2 - A Risk-Averse Multi-Stage Stochastic Programming Approach to Generation and Transmission Expansion Co-Planning

Sebastian Maier, University College London (UCL), London, United Kingdom, Yifeng Yu, Tohid Erfani

In the ever changing landscape of the electricity market, proper alignment for generation and transmission capacity expansion planning is crucial to meet future demand, mitigate financial risk and maintain grid stability. Traditional models often misestimate the risks involved, leading to potentially suboptimal investment decisions. Integrating risk aversion measures, such as CVaR (Conditional-Value-at Risk), into the planning process is a complex challenge. It requires ensuring time consistency in the planning process while trading-off an efficient capacity expansion decision. This paper proposes a time consistent multistage generation and transmission expansion co-planning model. The model employs a nested formulation of CVaR as a risk assessment metric and the economic impact of the planning decisions as the financial measure. The model is applied to the New England IEEE 39 bus test system to examine the impact of risk aversion on the strategies for time consistent optimal capacity expansion planning in a perfectly competitive electricity market. The results present the strategy transition in terms of different levels of risk aversion on optimal expansion decisions. These shifts in investment behaviour are consistent with practical considerations and real-world scenarios, emphasising the importance of appropriately considering risk aversion in electricity capacity expansion planning models. We compare time consistent and inconsistent models in the same settings to understand how risk measures impact investment decisions. The time consistent model results in lower investment levels, suggesting more conservative choices. This research has implications for policy-making, highlighting the importance of a nuanced understanding of risk in planning.

3 - Managing Basin-Scale Carbon Sequestration: a Tragedy of the Commons Approach

Joseph Duggan, University of Dayton, Dayton, OH, United States, Jonathan Ogland-Hand, Michael Hannon, Steven Anderson, Richard Middleton

Reaching net-zero will require gigatonne-levels of CO_2 sequestration. For example, recent models of the energy system in the United States suggest that up to two gigatonnes of CO_2 storage may be required in 2050. This amount of CO_2 injection is multiple orders of magnitude greater than current injection rates can achieve and will require a huge expansion of deployment of CCS that could lead to competition between firms that sequester CO_2. For example, given that formations within sedimentary basins generally allow lateral fluid flow, the induced pressure increase from one firm's CO_2 injection may limit another firm's ability to inject CO_2. In this way, basin-scale carbon sequestration has the two main hallmarks of a classic Tragedy of the Commons, where the storage resource is 1) non-excludable, in that multiple CO_2 storage operators may be permitted to inject into the same formation without overlapping CO_2 plumes but still cause pressure interference with each other, and 2) rival in consumption, meaning each firm's use of the geologic subsurface for sequestration purposes reduces other firms' ability to profitably sequesterCO_2 because of the increased pressure. Here, we explore the incentive implications of basin-scale carbon sequestration by modelling geologic CO_2 storage as a variant of the Tragedy of the Commons, a well-studied problem in the economic literature. CO_2 capture and storage (CCS) is an essential tool for meeting global climate goals, but the incentive effects, market design implications, and broader economic management strategies of CCS are underexplored.

4 - Day-ahead and reserve prices in a renewable-based power system: adapting electricity-market design for energy storage

Laureen Deman, Univ. Grenoble Alpes, CNRS, INRAE, Grenoble INP, GAEL, Grenoble, France, Afzal Siddiqui, Cédric Clastres, Quentin Boucher

Decarbonising the power mix will require investments in storage and flexibility options to replace the current carbon-intensive supply of reserves. This paper questions whether reserve-capacity markets can serve as a capacity mechanism for flexible technologies. A fundamental model of the day-ahead and reserve markets is used to investigate the evolution of reserve prices with large shares of renewable energy and storage. The model represents the current market design in Continental Europe with a centralised supply and platforms for the exchange of reserves. By becoming the main suppliers of reserve capacity, batteries have a noticeable impact on reserve prices. Their flexibility implies zero opportunity cost most of the time, meaning that the flexibility is not rewarded by the market. These results suggest that reserve-capacity markets cannot provide additional remuneration for flexible technologies and, thus, do not solve the missing-money problem in the context of the energy transition.

5 - Empowering Energy Communities: Balancing Technological, Economic, and Social Objectives through Optimization

Lia Gruber, Graz Unversity of Technology, Austria, Graz, Austria, Sonja Wogrin

Facilitating the transition to sustainable energy systems necessitates the active involvement of ordinary citizens, which can be achieved through energy communities. These communities enable collective energy production, consumption, storage, and trading, serving as multi-dimensional constructs involving various stakeholders. While often approached solely from a technological standpoint, energy communities inherently carry social and economic dimensions, impacting issues like energy poverty. To address these complexities, we propose a comprehensive optimization model that considers all dimensions through a multi-objective approach. Our model aims to optimize three key objectives. Firstly, it seeks to minimize power peaks within the energy community, minimizing strain on the grid. Secondly, it aims to minimize the overall cost of the energy community, considering factors such as operational cost, grid tariffs and energy purchasing. Thirdly, it prioritizes maximizing fairness for energy-poor members within the community, ensuring equitable access to affordable energy resources. It integrates diverse production and flexibility options, including biomass, photovoltaic, battery storage, and electric vehicles, while also incorporating grid constraints and tariffs as well as energy allocation between members. Grid tariffs and energy allocation methods implemented in the model are accordance with Austrian legislation. As implementation, subsidization, and regulation of energy communities have already been well established in the country. By optimizing trade-offs between technological, economic, and social objectives, our model seeks to guide the design and operation of sustainable and inclusive energy communities, advancing the transition towards a more decentralized and equitable energy landscape.

1 - Climate Smart Staffing for Harvesting Operations

Sanchita Das, University of Washington, Seattle, WA, United States, Masha Shunko, Leonard Boussioux

Problem Definition: We present our collaboration with the Washington Fruit Tree Research Center to design a capacity planner that enables dynamic resource allocation for fruit tree growers in response to weather and climate based yield uncertainties to maximize farmer's profit. Apple production is a 4 billion USD industry, and labor contributes 25-40% of input costs. Given the fluctuations in weather and climate due to global warming, the time of apple ripening (harvest window) is becoming erratic from year to year. The pre-season planned resource (labor, refrigeration) capacity is either under or over-utilized. We contribute a robust optimization technique that calculates and dynamically allocates labor to farms by predicting shifts in harvest dates due to weather changes. Methodology/Results: We combine a weather forecasting model with a climate adaptation model for apple fruit trees to predict fruit maturity (harvest) dates. We model a data-driven dynamic staffing optimization and robustify it using a distributionally robust optimization where ambiguity sets are determined based on the predictions from historical data. Managerial implications: Due to global warming, it is imperative that growers have a set of decision support tools to hedge against climate change. Our proposed capacity planning tool provides early alerts to farmers for dynamic staffing in response to weather based uncertainties to improve their preparedness and profitability.

2 - Data-Driven Stochastic Programming for Electric Vehicle Charging Station Location with Decision-Dependent Demand Learning

Huangrong Sun, The Ohio State University, Columbus, OH, United States, Xian Yu, Guzin Bayraksan

We consider a two-stage electric vehicle charging station location problem with uncertain customer demand, where the demand depends on the first-stage location decisions. We employ both parametric (e.g., exponential and linear regression) and nonparametric (e.g., kNN) models to describe the dependence between customer demand and location decisions and develop a two-step learning approach to fit the regression model. Using empirical residuals from the learning step, we construct a residuals-based sample average approximation problem to approximate the true two-stage stochastic program. Numerical studies are conducted on synthetic data and real-world data in New York State to evaluate result sensitivity and compare different approaches.

3 - Search Between the Lines: Field Experiment, Structural Estimation, and LLM-Based Optimization

Jin Liu, University of Science and Technology of China, Hefei, China, People's Republic of, Xingchen Xu, Yongjun Li, Yong Tan

In online marketplaces, consumers are typically presented with lists of products, allowing them to browse and search items of interest for further information before finalizing their purchases. Existing literature has explored consumer interactions with vertically arranged product lists; however, empirical evidence is lacking for horizontal lists, another prevalent format. Moreover, in specific sectors like online reading, text elements can significantly influence both the search costs and the expected utility derived from a product, complicating the analysis of these dual effects. To address the gap, we develop a sequential search model that integrates considerations of horizontal ranking, text-associated search costs, and text-influenced utility expectations. Utilizing data from a field experiment conducted on a prominent online reading platform, where books are displayed in a randomized horizontal order, we estimate our model to examine how horizontal rankings and text features impact consumer search behaviors and decision-making processes. Additionally, we propose a counterfactual policy, utilizing large language models, to enhance decision-making efficiency in such settings.

Computational Integer Programming

Invited Session

Computing Society

Chair: Chen Chen, The Ohio State University, Columbus, OH, United States

1 - Two-Column Probing for Mixed-Integer Programming

Chen Chen, The Ohio State University, Columbus, OH, United States

Probing involves tentatively testing values of variables in order to determine various implications. In mixed-integer programming probing is typically conducted on one binary variable at a time in the preprocessing stage, yielding implications that are useful for branch-and-cut algorithms such as conflicts, strengthened variable bounds, aggregations, and cutting planes. In this talk we consider the extension to two-column probing, where pairs of binary variables are tested in tandem (over their four possible configurations). Although such a procedure may yield more and stronger implications compared to standard probing, the computational load is substantially higher. We describe our attempt to navigate this tradeoff.

2 - Exploiting Symmetry in Risk-Averse Antibiotics Time Machine Problem

Burak Kocuk, Sabanci University, Istanbul, Turkey, Deniz Tuncer

Antibiotics time machine problem is a challenging combinatorial optimization problem that can be used to reverse the antibiotic resistance of the bacteria. The risk-averse version of this problem can be modeled as a mixed-integer linear program with scenarios and can be solved by adapting a scenario decomposition approach, which is based on no-good cuts. We develop stronger versions of the standard cuts that get rid of several solutions at the same time with few inequalities. We also study the underlying polyhedral set that involves the so-called symmetry breaking constraints and show how the aforementioned cuts can be further improved. Finally, we present the results of our computational experiments involving a real dataset to illustrate the efficacy of our approach.

3 - Augmenting Seq2Seq Models with Constraint Reasoning for Ambiguous Combinatorial Optimization

Macarena Navarro, Carnegie Mellon University, Pittsburgh, PA, United States, Willem-Jan Van Hoeve

We consider combinatorial optimization problems with ambiguous objectives or constraints, for which the functional form is not known. Learning the ambiguity in such problems is a generalization of inverse optimization. We propose to represent the ambiguous components using a neural network. While these could be linearized and added to an optimization model, that approach is typically not scalable. Instead, we propose using sequence-to-sequence models that learn from past decisions and, given an input specification, can directly generate similar solutions to solve the problem. To ensure feasibility of the generated solutions we embed a constraint reasoning layer that represents the known hard constraints of the model. Using a knapsack problem with unknown objective as a case study, we demonstrate that our approach can generate near-optimal solutions and can even outperform an omniscient greedy heuristic.

4 - Can an infeasible MIP solve itself?

Yuriy Zinchenko, University of Calgary, Calgary, AB, Canada

The analysis of why a specific MIP instance is infeasible formally can be reduced to computing an Irreducible Infeasible Subset (IIS) of the constraints. Unlike the case of LP, for MIP there is no useful duality that can be employed to facilitate such computations. The process of determining an IIS for MIP is typically handled with brute force, e.g., by use of deletion filters and alike, thus rendering IIS determination for a MIP into a much harder computational task. We will discuss one approach to optimizing this process and what components of this approach have made it into the newest version of Gurobi.

Empirical Research in Service Operations

Invited Session

Service Science

Chair: Jane Iversen, The Ohio State University, Columbus, OH, United States

Co-Chair: Yingchao Lan, University of Nebraska-Lincoln, Lincoln, NE, United States

1 - When does Continuity matter? Evidence from a health services setting.

Vishal Ahuja, Southern Methodist University, Dallas, TX, United States

The topic of continuity of care (CoC) has gained attention within the operations literature, especially recently. Studies have generally found a positive association between (greater) primary care CoC and (improved) outcomes such as 30-day readmissions. However, limited attention has been paid to how CoC interacts with other operational levers – that is, whether and how the benefits of continuity alter in the presence of other operational levers that managers may have at their disposal. Thus, we first study whether the benefits of CoC extend to mental healthcare. Importantly, we investigate continuity's relationship with four operational levers that have typically been studied independently– collocation of physical and mental health services, visit regularity, team familiarity and patient complexity. As America's largest integrated health system, the Veterans Health Administration offers an ideal setting to investigate these questions. We analyze more than 73,000 patients – over an 11-year period – who suffer from chronic conditions and show evidence of mental illness. We find that CoC is associated with improvement in hospitalizations, length of stay (LOS), 30-day readmits, and suicidal behavior. For example, 1 StDev increase in CoC is related to 8.2% average reduction in LOS, equivalent to $7 million annually. We also find that continuity has a substitutive relationship with collocation, familiarity, and regularity, but a complementary relationship with complexity (that is, the benefits of CoC are further enhanced for severe patients). Our work offers practical insights into where to target CoC and, broadly, how to design an operationally efficient system.

2 - Revving Up Retention: Analyzing the Influence of the Introduction of Food Delivery Services on Driver Behavior

Michael Dwyer, Iowa State University, Ames, IA, United States, Sukrit Pal, Thu Trang Hoang, Chris Tang

To sustain growth amidst increasing competition, ride-hailing platforms often introduce adjacent services, like food delivery, to their mobile apps for customers and drivers. However, the impact on drivers' choices between ride-hailing and new adjacent services remains understudied, motivating this project. By analyzing data from a ride-hailing platform in Vietnam, where a new food delivery service was introduced in two cities at different times, we used difference-in-difference with robustness checks to examine drivers' choices. Our analysis found that hybrid drivers, those offering both ride-hailing and food delivery services, saw an increase in revenue and worked more hours. We also found that these effects varied between part-time and full-time hybrid drivers. Hybrid drivers opted for shorter rides, clustering their operations. Meanwhile, dedicated drivers providing only ride-hailing services chose longer rides. The introduction of the adjacent food delivery service reduced labor supply disparities between part-time and full-time drivers. However, our study indicates "cherry-picking" behaviors among hybrid drivers with shorter rides, while dedicated drivers demonstrated a preference for longer rides. The adjacent service introduction created a potential segmentation in the driver pool and created new risks to service operations for the platform.

3 - Multi-Channel Healthcare Operations: The Impact of Video Visits on the Usage of In-Person Care

Tan (Suparerk) Lekwijit, W. P. Carey School of Business, Arizona State University, Tempe, AZ, United States, Hummy Song, Christian Terwiesch, Krisda Chaiyachati

Healthcare organizations have increasingly adopted video visits as an alternative care channel that offers greater convenience and holds promise for improving patients' access to care. Despite the growing use, the impact of a new digital channel on care demand within existing physical channels has not been thoroughly investigated, especially in the primary care context of a traditional healthcare organization. We study a large healthcare system that made video visits available to a subset of its patients for primary care needs, prior to the COVID-19 pandemic. Using a difference-in-differences approach and visit data spanning over 9.5 million patient-months, we find that the introduction of video visits increases the demand for in-person primary care provider (PCP) visits by 20% and the demand for emergency department (ED) visits by 30%. When considering only patient-initiated visits, we find that the introduction of video visits increases the overall number of care initiations but does not affect in-person care initiations, suggesting that patients initiate care through video visits for care needs that may have otherwise gone unattended. Furthermore, we find that the increase in in-person demand arises primarily from patients who have poorer access to in-person care, as measured by distance and provider busyness. Lastly, compared to in-person visits, we find that video visits are less likely to provide care that can successfully conclude a care episode, especially when the medical condition is acute. Our findings have important capacity and revenue implications for healthcare organizations that are considering offering video visits as an additional care channel.

Computational/Statistical Methods for Uncertainty Quantification: Part II

Invited Session

Quality, Statistics and Reliability

Chair: Moses Chan, Northwestern University, Evanston, IL, United States

Co-Chair: Ozge Surer, Miami University, Oxford, OH, United States

1 - Modeling High-Dimensional Outputs with Heterogeneous Noise Structure

Moses Chan, Northwestern University, Evanston, IL, United States

Computer models, or simulators, are indispensable in studying physical systems. Modern computer models generally are time-consuming to run and potentially produce noisy high-dimensional outputs. The calibration of such a computer model is facilitated by the use of fast surrogate models. This talk presents the latent component Gaussian process that leverages a basis representation of the output and models each latent component as a Gaussian process. The resulting formulation admits a general error covariance matrix of the noise, extending previous works which assume homogeneous error variance across the outputs. With an appropriate linear transformation of the output, this method provides exact inference in its prediction without incurring significant additional computational costs. We demonstrate the strength of this method through a set of numerical experiments and a case study involving the emulation of a viscous anisotropic hydrodynamics model used in heavy-ion collision simulations.

2 - Co-Active Subspace Methods for the Joint Analysis of Adjacent Computer Models

Kellin Rumsey, Los Alamos National Laboratory, Chicago, IL, United States

Active subspace (AS) methods are a valuable tool for understanding the relationship between the inputs and outputs of a Physics simulation. In this paper, an elegant generalization of the traditional ASM is developed to assess the co-activity of two computer models. This generalization, which we refer to as a Co-Active Subspace (Co-AS) Method, allows for the joint analysis of two or more computer models allowing for thorough exploration of the alignment (or non-alignment) of the respective gradient spaces. We define co-active directions, co-sensitivity indices, and a scalar "concordance" metric (and complementary "discordance" pseudo-metric) and we demonstrate that these are powerful tools for understanding the behavior of a class of computer models, especially when used to supplement traditional AS analysis. Details for efficient estimation of the Co-AS and an accompanying R package (concordance) are provided. Practical application is demonstrated through analyzing a set of simulated rate stick experiments for PBX 9501, a high explosive, offering insights into complex model dynamics.

3 - Rational Kriging

Roshan Joseph, Georgia Tech, Atlanta, GA, United States

I will talk about a new kriging method that has a rational form. It is shown that the generalized least squares estimator of the mean from rational kriging is much more well behaved than that of ordinary kriging. Parameter estimation and uncertainty quantification for rational kriging are proposed using a Gaussian process framework. I will also discuss a generalized version of rational kriging, which includes ordinary and rational kriging as special cases. Extensive simulations carried out over a wide class of functions show that the generalized rational kriging performs on par or better than both ordinary and rational kriging in terms of prediction and uncertainty quantification. The potential applications of the new kriging methods in the emulation, calibration, and optimization of computationally expensive models will be illustrated with real and simulated examples.

Data Science and AI for Informing Decisions in Mission Critical Systems

Invited Session

Quality, Statistics and Reliability

Chair: Mingyang Li, University of South Florida, Tampa, FL, United States

Co-Chair: Qingpeng Zhang, City University of Hong Kong, Kowloon, Hong Kong

1 - A Reinforcement Learning Approach to Network-level Maintenance Planning of Co-located Road and Water Infrastructures with Interdependencies

Bingjie Wang, UNIVERSITY OF SOUTH FLORIDA, Tampa, FL, United States, Hung Nguyen, Qing Lu, Qiong Zhang, Mingyang Li

The complex physical and operational interdependencies between co-located pipes and roads pose significant challenges in determining optimal maintenance actions for the deteriorating water infrastructure (WI) and transportation infrastructure (TI). For example, traffic load could exacerbate the co-located pipe failure rates, and the pipe's failure could in turn cause the blockage of its co-located roads, potentially leading to widespread traffic disturbances, incurring high corrective maintenance costs, user costs, and traffic control costs. Many existing maintenance works focus on studying a single system, such as WI or TI, and there is a lack of research to investigate the joint maintenance of co-located WI and TI with complex interdependencies. In this study, we propose a network-level maintenance decision-making framework for jointly optimizing the maintenance actions of TI and WI, consisting of a large number of co-located roads and pipes with both physical and operational interdependencies. Given the large action space inherent in network-level decision-making, a reinforcement learning approach is considered to determine the optimal maintenance actions across the networks, aiming to enhance cost efficiency and infrastructure robustness. To illustrate the proposed work and demonstrate its performance, a case study based on the co-located TI and WI in Ybor City, Tampa, is provided to showcase the cost-efficiency of the proposed maintenance strategies as compared to some existing benchmarks that neglect the complex interdependencies between TI and WI.

2 - A Deep Learning Enhanced Probabilistic Approach to Predicting Discharge Outcomes of Post-acute Care Residents in Skilled Nursing Facilities

YULUN XU, University of South Florida, Tampa, FL, United States, Nazmus Sakib, Hongdao Meng, Nan Kong, Kelly Smith, Mingyang Li

Predicting the discharge outcomes and their timings of the post-acute care (PAC) residents from skilled nursing facilities (SNFs) is essential for improving quality care, maintaining residents' functional status, and enhancing their chances of successfully returning to the community, private homes or lower-level care settings. However, it could be challenging due to random SNF dwelling duration with multiple discharged dispositions (e.g., community, re/hospitalization), as well as the influence of varied individual characteristics, diseases, and functional performance.

Existing work mainly focused on predicting a single discharge outcome and its timing in the hospital environments, and many of existing prediction models can only provide deterministic prediction outputs. We propose a deep learning enhanced probabilistic prediction model which is capable of accurately predicting resident-level time-to-discharge outcomes with multiple discharge dispositions. The proposed model takes advantage of deep learning’s capability of establishing nonlinear functional mapping and further allows the probabilistic assessment and prediction of time-to-discharge outcomes with meaningful model interpretations. A real case study is provided to illustrate the proposed work and demonstrates its superior performance (e.g., prediction performance, model interpretation) over existing benchmarks.

3 - Optimal Bidding in Online Display Advertising: A Deep Reinforcement Learning Model for Mobile Gaming Market

Mengzhuo Guo, Sichuan University, Chengdu, China, People's Republic of, Qirui Yang, Congde Yuan, Qingpeng Zhang, Frank Chen

When a user opens a website or app, there are often several advertisements interspersed. Whenever such an advertisement appears, loads, and is seen on a user's screen, it is referred to as an impression. For advertisers, an impression signifies an opportunity for their ads to be viewed. Real-time bidding (RTB) has emerged as a prominent paradigm, allowing advertisers to procure available impressions through instantaneous automatic auctions. In RTB, the goal for advertisers is to maximize the total revenue generated from the impressions they win while considering constraints such as budget. Due to the difficulty in estimating the value of impressions and the bids of competitors, determining the optimal bid for each impression becomes a highly challenging problem for advertisers. To address the sparse reward issues causing an unstable learning process, we first propose a novel definition of impression value under the background of the online mobile gaming market, which takes into account players' in-game purchase tendencies, conversion revenue, and publisher characteristics. In addition, to enhance the interpretability of the strategy, we divide the bidding process into two parts: the first part employs reinforcement learning techniques to obtain a two-dimensional vector based on an optimization problem. This vector contains information on both the risk of overpaying and the likelihood of securing a bid. We conduct comprehensive offline experiments and set up an online A/B testing experiment. Real-world experiments with more than a hundred million users during a week validated that ACRL improved the return on investment by 83.89%.

Optimization for Smart Grids

Contributed Session

Chair: Shahab Sadri, University of Louisville, Louisville, KY, United States

1 - A Real Options Valuation to Commercialize Wave Energy Farms

James DiLellio, Pepperdine Graziadio Business School, Malibu, CA, United States, Effie Ashu

Waves are one of the most abundant sources of renewable energy, yet the technology needed to profitably harvest it remains nascent in the commercial markets. Wave energy is obtained by converting kinetic energy from ocean waves into electricity. One of the big challenges in commercializing wave energy lies in the uncertain investment needed to increase the Technology Readiness Level (TRL) to 9, the level at which technology is considered ready for widespread deployment in the market while properly addressing the economic and technical challenges of energy production at scale. Consequently, to analyze these investments we use the concepts of real options, treating the investment as an out-of-money compound and deferred option starting at TRL 6. A real option valuation is conducted on these risky investments amid uncertain wholesale electricity prices. We show that the real option results may turn a negative Net Present Value (NPV) project without managerial flexibility into a positive one due to the expected option value. Additionally, we show that with sufficient carbon credits as a percent of capital expenditures, the project becomes even more favorable for investment and reduces the risk of negative NPV further. The results of this research support government decisions on the need for additional investment and/or incentives for renewable energy projects. We also suggest the possibility of public-private partnerships for any nascent technology like wave energy that still requires additional investment in research and development to reach TRL 9.

2 - Impact of Climate Change on Battery Energy Storage: A Case Study of MISO

Zhenggao Wu, University of Waterloo, Waterloo, ON, Canada, Stanko Dimitrov, Michael Pavlin

Climate change will have multiple impacts on energy markets by changing demand patterns and changing supply patterns --- by indirectly increasing renewable penetration and changing the dynamics of the supply from renewable sources (e.g., when and where it is windy/cloudy). Battery energy storage systems (BESSs) are one way to effectively manage intermittency from renewable energy. However, their profitability and incentive to participate in markets are susceptible to both the magnitude and frequency of price variation. This paper investigates the impact of climate change on a BESS operating in a North American deregulated electricity market. We propose a robust optimization model to determine the operating policy for a BESS over an 80-year period, considering various climate projections. We reformulate the robust optimization model to an equivalent linear program that allows us to numerically explore 108 climate scenarios. Our empirical study focuses on the Midcontinent Independent System Operator (MISO) market in the U.S., aiming to determine the optimal operation of the BESS using our model. The findings reveal that precipitation is the primary driver of variability in electricity prices, which varies across climate scenarios and geographical locations. Furthermore, climate change could increase arbitrage opportunities and operational incomes through arbitrage in Northern MISO, likely due to the region's heightened sensitivity to wind variations.

3 - Fair Control Policy for Shared Battery Energy Storage

Chaiyoung Lee, Yonsei University, Seoul, Korea, Republic of, Soongeol Kwon

With the increasing interest in improving renewable energy penetration and sustainability, Battery Energy Storage (BES) has been widely adopted. Shared BES, in particular, offers advantages in terms of operational and cost efficiency compared to individual BES, and thus, the installation of shared BES has been accelerated. However, to promote and sustain the shared BES, it is essential to ensure fair access and guarantee the financial benefits of sharing BES across users. This study aims to design a control policy that allows users to share BES with fairness and benefits by incorporating the uncertainties and variability existing in solar energy generation, electricity demand, and electricity prices. Specifically, a two-stage stochastic mixed linear programming is proposed to derive equitable charging and discharging thresholds that can be used as a rule-based control policy. The proposed control policy is validated and evaluated through comprehensive numerical experiments where the findings emphasize its capability and practicability to enhance the operations of shared BES.

4 - Managing residential electricity consumption with buyback price in a smart micro grid

Shahab Sadri, University of Louisville, Louisville, KY, United States, Lihui Bai

This research aims to study the residential electricity load in a smart grid consisting of a microgrid with solar panels and battery storage systems under the net metering program. The system allows residents to sell their excess electricity back to the grid. We study the smart grid from the perspectives of households as well as the utility company. In the Social Welfare model (SW) model, the utility company aims to maximize the social welfare of the entire network, which includes the households' convenience minus the electricity generation cost. On the other hand, in the User Equilibrium model (UE) model, each household maximizes his or her utilities in a Nash Equilibrium game. In the real world, the users' consumption is affected by the pricing scheme that the utility company charges. Therefore, we model the hierarchy as a Price-Responsive User Equilibrium (PRUE) model. In the PRUE model, each household maximizes its utilities in response to the pricing scheme imposed by the utility company. We show that alternative pricing schemes can achieve the maximum possible social welfare and, therefore, can be further optimized using secondary objectives. The latter results in different users' consumption behavior. Numerical results with various pricing schemes and sensitivity analysis are to be reported.

ESG Strategies and Corporate Performance

Contributed Session

Chair: Yang Li, Montclair State University, Montclair, NJ, United States

1 - Heterogeneity Aspiration Performance Gaps and Corporate Environmental Responsibility: A Comparison between Family Firms and Non-family Firms

Xuan Wang, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Wei Sun

Fulfilling environmental responsibility is an important practice for corporate transformation and upgrading, as well as a crucial strategic decision for businesses. However, existing literature lacks analysis from the perspective of performance feedback in examining the key factors that drive companies to fulfill environmental responsibilities. Based on performance feedback theory, this study explores the impact of heterogeneous aspiration performance gaps on corporate environmental responsibility and compares the similarities and differences in this relationship between family firms and non-family firms. Using data from Chinese A-share listed companies from 2009 to 2022, the study finds that historical aspiration performance gaps and social aspiration performance gaps have different impacts on corporate environmental responsibility. When distinguishing between types of companies, family firms demonstrate different moderating effects on this relationship. This study expands the understanding of how aspiration performance gaps influence corporate environmental responsibility and provides valuable insights for companies in formulating their environmental responsibility strategies, especially regarding the differentiated approaches that should be taken based on the type of enterprise.

2 - Do Well by Doing Good? The Trend and the Operational, Market Valuation, and Employee Welfare Implications of Rank-and-File Employee Ownership Disclosure

Runqing Yang, Boston University, Boston, MA, United States, Mohamed Balboula, Nuo Yuan, Jack Moriarty, Dokyun Lee

Employee ownership (EO) is increasingly recognized for its potential to enhance firm performance, employee well-being, and innovation. Despite these advantages, a critical gap remains in understanding how public companies disclose rank-and-file EO and how such disclosures impact key stakeholders, particularly investors, employees, and customers. This gap is even more pronounced in light of recent regulations like the SEC's 2020 human capital disclosure rule. This study directly addresses this gap by analyzing EO disclosures in 10-K filings of U.S. public firms implementing NCEO-validated ESOPs from 2010 to 2023. We employ a multi-step approach. First, we utilize keyword-based text extraction to isolate relevant sections within extensive corporate reports focusing on EO terms. Next, we leverage advanced large language models (LLMs) to construct various EO disclosure indexes, quantifying the quality and depth of corporate disclosure. Finally, our econometric analysis, accounting for potential LLM-generated measurement errors, explores how these disclosure indices correlate with market valuation (stock returns and risk), operational performance (profitability and productivity), and employee welfare (measured through Glassdoor ratings and turnover rates). This research not only extends the knowledge base on corporate disclosure and human resource management but also provides actionable insights. It can help corporate managers and policymakers leverage EO disclosure practices not just for compliance but as a strategic asset to boost firm performance and stakeholder engagement, particularly in attracting and retaining talent, and influencing investors and customer behavior.

3 - Analytics on Puzzling Relationship Between ESG and Corporate Financial Performance

Akira Maeda, The University of Tokyo, Tokyo, Japan, Hiroshi Ishijima

The impact of ESG (Environmental, Social and Corporate Governance) and CSR (Corporate Social Responsibility) on corporate performance has long been discussed. People are mainly interested in whether or not ESG helps improve corporate performance. There are many academic studies on this topic, but the results are not uniform: some studies show a positive relationship between the implementation of ESG activities and corporate financial and business performance indicators e.g., profit, revenue, return on assets (ROA), and return on equity (ROE). On the other hand, some studies argue that there is a negative relationship between ESG and corporate performance indicators. Whichever conclusion is reached, most of the research to date has been a discussion of whether the relationship is positive or negative, not the idea that it is essentially a mixture of both effects. The conclusion is a choice between the two.

This paper is an attempt to provide a new perspective for understanding these mixed results thus far. We propose the hypothesis of a U-shaped relationship as a hypothesis that can support both sides of the argument. The authors have reported on this hypothesis up to that point in several seminars and presentations including Maeda and Ishijima (2023a) as well as a short article of Maeda and Ishijima (2023b). In this paper, we report our latest findings, especially on the theoretical analysis: After testing out hypothesis using data from the Toyo Keizai CSR Ranking, which is a comprehensive survey report on Japanese companies, we present an innovative theory.

4 - Managing Sustainable Environment, Social, and Governance (ESG) Activities in Health Care Organizations Using Goal Programming Model

Chang Won Lee, Hanyang University Business School, Seoul, Korea, Republic of

This paper is to develop a goal programming (GP) model that aids in managing sustainable environment, social, and governance(ESG) activities in health care organizations. The model is developed on the ESG related data from health care organizations. The suggested model will utilize a GP model to reflect the multiple, conflicting ESG activities. The ESG activity goals are decomposed and prioritized and the model results and findings are discussed. This suggested GP model will provide strategic insights in health care ESG planning and similar planning settings.

5 - Attention Management by Salience in ESG Report

Yang Li, Montclair State University, Montclair, NJ, United States

ESG reports have become an essential part of corporate communication and serve as a tool for firm reputation and impression management. Based on the salience theory, this study employs a deep learning-based visual attention algorithm to analyze if and how firms with different levels of commitment to sustainability manage the readers' attention by manipulating bottom-up attention transmitted through environmental, social, and governance (ESG) reports. Our results show that reports from less committed firms are more likely to show distracting patterns with an overwhelming amount of salient points and regions populated across all pages. Stakeholders encountering reports with numerous distracting elements should exercise caution and suspect that the company may not accurately represent its commitment to ESG.

Advances in Reinforcement Learning

Contributed Session

Chair: Mohammad Rostami, Alarm.com, Arlington, VA, United States

1 - Link Prediction Modelling in Human Trafficking Networks - A Survey

Hasini Balasuriya, University of Louisville, Louisville, KY, United States, Monica Gentili

Link prediction models play a key role in analyzing complex networks, forecasting missing or future connections, and revealing the dynamics of illicit trafficking networks. While numerous surveys have examined general link prediction modeling, research specifically exploring these models' application to illicit networks remains sparse. This study contributes a thorough literature review that addresses this deficiency by evaluating how effectively link prediction models can identify missing links in illicit networks. Our aim is to deliver a precise, well-organized overview that advances understanding of the potential of these models in disrupting illicit activities.

2 - State augmented reinforcement learning for constrained Markov games

Soham Das, Texas A&M University, College Station, TX, United States, Ceyhun Eksin

We present a new approach for solving constrained Markov games utilizing a state-augmented description of constrained reinforcement learning. We consider a Markov game with identically interested agents with local cost constraints that depend on the action and state coupled over time. These games, for example, serve as a formal framework to study autonomous teams with local energy and time constraints. We augment the state space of the Markov game with Lagrange multipliers and reinterpret primal dual methods as the portion of the dynamics that drives the multipliers forward. Our algorithmic framework assumes that agents can solve the unconstrained Lagrangian Markov game to an approximate Nash Equilibrium. Then our primal dual solver guarantees feasibility for the constrained Markov game asymptotically, which still converging to an approximate Nash equilibrium for the game.

3 - Integrating Reinforcement Learning and Stochastic Network Design

Fatemeh Sarayloo, University of Illinois Chicago, Chicago, IL, United States, Teodor Gabriel Crainic, Walter Rei

This research aims to explore the integration of reinforcement learning (RL) algorithms and optimization methods to address stochastic network design problems. The goal is to enhance the synergy between reinforcement learning and optimization methods to effectively explore extensive solution spaces. The anticipated outcomes promise to significantly influence the field by offering more robust and efficient solution methods for complex, large-scale optimization problems in uncertain environments.

4 - Learning Efficiently in Data-Scarce Regimes

Mohammad Rostami, Alarm.com, Arlington, VA, United States, Mohammad Rostami

The unprecedented processing demand, posed by the explosion of big data, challenges researchers to design efficient and adaptive machine learning algorithms that do not require persistent retraining and avoid learning redundant information. Inspired from learning techniques of intelligent biological agents, identifying transferable knowledge across learning problems has been a significant research focus to improve machine learning algorithms. In this talk, we explain how the challenges of knowledge transfer can be addressed through embedding spaces that capture and store hierarchical knowledge.

We first focus on the problem of cross-domain knowledge transfer. We explore the problems of zero-shot learning and unsupervised domain adaptation and explain how similar ideas can be used to address both learning settings. We then investigate the problem of cross-task knowledge transfer in sequential learning settings. We address the problem of lifelong machine learning using generative experience replay, where the goal is to learn sequential tasks without forgetting. We develop a method to overcome the problem of catastrophic forgetting within a continual learning setting of deep neural networks by enforcing the tasks to share the same distribution in the embedding space.

Finally, we focus on current research directions to expand the past progress and plans for the future research directions. Through this talk, we demonstrate that despite major differences, problems within the above learning scenarios can be tackled using a unifying strategy that allows transferring knowledge effectively.

5 - Learning Sentence Similarity Using Siamese LSTM Network and Traditional Approaches

Sajede Farahani, University of Wisconsin-Milwaukee, Milwaukee, WI, United States

Community Question Answering platforms such as Quora, Stack Overflow, and others offer users a venue to engage with experts and acquire precise and reliable answers to their inquiries. To mitigate the delay between posting a question and receiving a response, one strategy involves retrieving analogous past questions from the archives of these platforms. Identifying semantic similarity presents a complex challenge due to the vast array of potential expressions available in natural language, alongside its inherent ambiguity. This study adopts two approaches. Firstly, we utilize feature engineering alongside various machine learning algorithms such as Random Forest, XGBoost, and logistic regression to assess the performance of these models in identifying similarities among pairs of questions. Secondly, we introduce a Siamese Long Short-Term Memory (LSTM) network to determine semantic similarity between current and archived questions, demonstrating its superior performance compared to previous methods.

Innovative Approaches in Decision Making and Optimization

Contributed Session

Chair: Arik Sadeh, HIT Holon Institute of Technology, Holon, Israel

1 - Do People Underweight the Supply Line? An Eye Tracking Investigation

Heetak Shah, Indian Insititute of Technology Bombay, Mumbai, India, Tarikere T. Niranjan, Enno Siemsen

This study investigates possible *rational* reasons behind supply line "underweighting", well-known as a cognitive bias in supply chain decision-making. We believe that much of the notoriety surrounding this "bias" is perhaps misplaced, at least in contemporary supply chain decision making. We employ an eye tracking based experiment to understand how people consider the supply line. The main goal of this study is to understand if people fail to recognize the supply line or if they recognize it but deliberately disregard the information. This experiment further aims to understand if people disregard the supply line commensurate with the reliability or timeliness of the supply line. We also look at a possible solution to dampen the underweighting behavior in case of an untimely or unreliable supply line. This study's results will help increase our understanding of this underweighting behavior. The findings will also provide useful directions for future researchers to build on the vast prior literature in this domain and harness the insights for a better understanding of this important application area.

2 - Optimizing Inspection Strategies in Genetic Manufacturing Systems with Parallel Synthesis Lines Using Markov Decision Process

Mohammad Maydanchi, Auburn University, Auburn, AL, United States, Gregory Purdy, Daniel F. Silva

In recent years, synthetic biology has advanced significantly, with genetic engineering becoming an increasingly vital component of biotechnology. Creating an efficient production process for genetic constructs is crucial for the synthetic biology industry. Genetic Manufacturing Systems are a recent innovation that aim to streamline this process. Similar to other manufacturing processes, inspections are necessary for Genetic Manufacturing Systems to ensure high-quality outputs. This study uses a Markov decision process to model a Genetic Manufacturing System and determine the appropriate inspections for DNA fabrication. The model represents a multi-stage inspection allocation problem and examines how modifying a Genetic Manufacturing System's characteristics impacts the optimal inspection strategies. Additionally, we examine a Genetic Manufacturing System that creates two fragments simultaneously in two parallel synthesis lines and combines them to produce a longer fragment assembled based on the Gibson assembly protocol. The mathematical model presented provides a valuable tool for designing an optimal inspection strategy for Genetic Manufacturing Systems. This research has significant implications for professionals in the synthetic biology industry, as the findings can be used to optimize the production of high-quality genetic constructs.

3 - Network-driven airline on-time performance prediction with dynamic delay propagation

Yi Tan, The University of Alabama in Huntsville, Huntsville, AL, United States, Yajun Lu, Lu Wang

We study the impact of network information of recent delayed flights for airline's on-time performance prediction. As a critical performance indicator of air transport systems, flight delays have attracted great attention to the OM researchers. However, the impact of recent delays of other flights within the entire airport network remains largely unexplored. By addressing multiple challenges in airline operations, we proposed a novel network-based approach, which can derive a time-dependent delay risk score for each airport. Empirical experiments show that integrating this airline network extracted feature with a group of intrinsic features from the airline operation literature can significantly improve the flight delay detection ability. Also, SHAP analysis shows that the network extracted feature ranked as the most important among 13 benchmark predictors.

4 - An analysis on evolution rate of legal case citations in India

Kumar Sarthak, Indian Institute of Technology Delhi, New Delhi, India, Shaurya Shriyam, Nomesh Bolia

Ever changing citation behaviour of legal case citations results in a dynamic characteristic in the analysis of the citation network. The notion of landmark cases or important cases evolves with time according to the cases being cited as precedents in the judgment of the present case. Prior research has mainly focused on a statistical analysis of the network by applying traditional network metrics to quantify the importance of cases. Most statistical concepts and formalisms fail to capture the temporal evolution of the network. In this paper, we investigate the rate of evolution of landmark cases based on the time-varying graphs (TVGs) spanning successive time intervals. Additionally, we explore the structural properties of legal cases to capture the definition of importance by employing centrality measures such as relative degree, betweenness and longevity. Moreover, we evaluate the modularity of the network to detect the community structures in the network. For this study, we curate a large dataset of judgments from the Supreme Court of India on Article 300A (right to property) of the Indian Constitution. Our analysis shows that the temporal analysis, in association with the analysis of structural properties, provides a deeper understanding of the nuanced dynamics within the real-world dataset. Our work also identifies how the complexity of the citation network is directly proportional to complexity in legal cases due to multiple and hierarchical citations in cases and its evolution over time.

5 - Empirical and Theoretical Results on Bertrand Duopoly with Interaction

Arik Sadeh, HIT Holon Institute of Technology, Holon, Israel

The Bertrand competition is an arena where firms compete in the price market. In Cournout games, firms compete by setting their quantities in the market. The attractiveness of Bertrand's games in economics is the visibility of prices to all competitors.

Games are commonly used in markets with a few decision makers where the playing firms see downward demand functions.

In this study, we analyze two firms in a duopoly market. The firms sell nonidentical products that satisfy the same customers' needs.

The demand function for each firm is based on its price and the competitor's price, along with an interaction of both prices on each demand. We show that there is more than one Nash equilibrium point that leads to stability questions, The role of the cost function, its functional form, and parameters impact the number of potential equilibrium points. This is an essential issue in markets with technological and innovative products.

The dynamics of Bertrand's games can serve as a mechanism to reveal the costs of the competition.

Cybersecurity Impacts and Strategies

Contributed Session

Chair: Madison Evans, Auburn University, Opelika, United States

1 - Demonstrating Cyber-Physical Attacks in a Multi-Fidelity Manufacturing Digital Twin Environment

Madison Evans, Auburn University, Auburn, AL, United States, Gregory Purdy

Cybersecurity has grown increasingly crucial due to the number of reported cyber incidents that occur every year. Every industry is vulnerable to the threats posed by cybercriminals. Some industries, like manufacturing, face additional challenges due to the prevalence of cyber-physical systems. These systems have components in both the physical and digital worlds, which create new and dangerous vulnerabilities for cybercriminals to exploit. Studies indicate that conducting security testing on these types of machines can lead to significant and costly damage. Manufacturers need a regulated and secure environment that closely emulates the physical properties of the system to investigate cyber-physical attacks and defense mechanisms. A digital twin of the system can be used to create such an environment; however, it introduces the question of the extent of modeling fidelity needed to secure systems. In this presentation, we will demonstrate a cyber-physical attack in a Digital Twin Environment with varying levels of fidelity. We will examine and differentiate the conclusions that can be made from the results at these different levels. We will use these results to construct a Multi-Fidelity Digital Twin that can be incorporated into a Cyber-Physical Manufacturing Range.

2 - The Impact of Security-Related Stress (Srs) on ICT-Enabled Productivity from The Transactional Model of Stress and Coping and Holistic Stress Model Perspective

Roya Ashrafidehkordi, University of North Texas, Denton, TX, United States

Information security demands within the organizations could lead to security-related stress (SRS), one of the critical issues in the information systems field in the past years. Previous research mostly worked on how this kind of stress would lead to employees violating the security policies and focused on the dark side. Given that, the present study will explore the influence of the SRS on ICT-enabled productivity to figure out the bright side of coping with SRS. The study integrates two theoretical frameworks, the transactional model of stress and coping and the holistic stress model, to examine the employees' appraisal mechanism, psychological perception, coping mechanism, and finally, the impact of this whole path on ICT-enabled productivity. This research would also apply different strategies for coping processes that would offer a comprehensive understanding of the multifaceted nature of stress and its impact on individual well-being and productivity. The research contributes to the existing literature by digging into the bright side of security-related stress and addressing the complex interrelationship between security-related stress and ICT-enabled productivity. Overall, the article comprehensively explores various coping mechanisms to advance understanding of this critical intersection.

3 - Does the CEO regulatory focus matter in containing data breaches? Evidence from US-listed firms

Amit Kumar, Indian Institute of Management Ahmedabad, Ahmedabad, India, Adrija Majumdar, Indranil Bose

In the current times, data breaches are pervasive, affecting many organizations operating in diverse sectors. Data breaches cause significant damages, including financial setbacks, reputation loss, erosion of customer trust, and legal liabilities. Surprisingly, top management still treats data breaches and cybersecurity as a technical function rather than a strategic one. This misconception and the enormous costs of containing a data breach underscores the need for CEOs to lead cybersecurity efforts. Data breach literature has neglected the impact of CEOs on data breaches, and our research tries to fill this gap. Drawing on regulatory focus theory, we examine how CEO regulatory focus- promotion and prevention- impacts data breach risk. We contextualize our study by investigating the moderating role of IT investment in this relationship. Using the data of US-listed firms over six years (2016-2021), we find that CEO promotion focus reduces data breach risk, while CEO prevention focus increases the data breach risk. We also find that IT investment mitigates the impact of both the CEO promotion focus and the CEO prevention focus on data breach risk. By emphasizing the containment of data breach risk as a firm performance metric, our study highlights the importance of cybersecurity leadership at the top management level. We contribute to the literature on data breach and regulatory focus by integrating CEO motivation (measured through regulatory focus) and IT investment with data breach dynamics while providing insights for practitioners and policymakers in cybersecurity strategies.

4 - The Impact of Information Security Investment on Firm Financial Risk: The Role of Board Diversity

Niyanta Sookraj, Auburn University, Auburn, AL, United States, Yen-Yao Wang, Xin Luo

As information security threats rampage through the digital era, their impact on firm financial risk has become increasingly concerning. Despite the considerable surge in information security investments, data breaches have continued to persist alongside other security concerns, raising doubts about the efficacy of these investments. This study examines the relationship between information security investments and firm financial risk through the lens of corporate governance in the form of board diversity. The value of board diversity lies in its potential to bring about a broader range of perspectives, expertise, and innovation through the facilitation of discussions and the exchange of ideas, thus strengthening the board's problem-solving and decision-making abilities. Specifically, we focus on one element of cognitive diversity – board tenure diversity. To the best of our knowledge, this is the first study to examine board tenure diversity in the context of firm financial risk. Utilizing a ten-year panel encompassing 7,892 firm-year observations across 1,071 unique firms, we uncover that information security investments lower financial risk for firms. Furthermore, we find that board tenure diversity is a significant moderator in the relationship between information security investments and firm financial risk, indicating that the board's composition can play a strategic role in risk management. Our results suggest that firms should prioritize information security investments and consider board composition to enhance the effectiveness of these investments. By incorporating board tenure diversity, firms can more effectively navigate the complex landscape of information security threats.

5 - Filling the Blanks: Enhancing Vulnerability Assessment in Dark Hosts

Mohammad Abdullah, The Ohio State University, Dublin, OH, United States, Theodore Allen, John McCarty

Our research addresses significant vulnerabilities in cybersecurity assessments, focusing on 'dark hosts'—network hosts that evade regular scans. Analyzing a dataset from a major Midwest institution featuring over 48,495 hosts, we found that more than 50% of the hosts went unscanned in any given month. To address these gaps, we deployed machine learning models that effectively predict potential vulnerabilities using historical scan data. Our classification models successfully identified critical vulnerabilities with over 91% accuracy. By leveraging information such as the host's operating system, past scan data, and organizational context, these models significantly enhance the predictability of vulnerabilities in dark hosts. This not only improves our ability to secure network infrastructures but also provides crucial insights to help cybersecurity management teams in any organization make better-informed decisions regarding their next steps in vulnerability management and prevention.

Robust and Ethical Market Design

Invited Session

Auctions and Market Design

Chair: Juba Ziani, Georgia Tech, Atlanta, GA, United States

Co-Chair: Rachel Cummings, Columbia University, New York, NY, United States

1 - Equilibria of Data Marketplaces with Privacy-Aware Sellers Under Endogenous Privacy Costs

Diptangshu Sen, Georgia Institute of Technology, Atlanta, GA, United States, Jingyan Wang, Juba Ziani

We study a two-sided data ecosystem comprised of an online platform, users who may want to participate on the platform, and downstream data buyers who look to purchase data from the platform. The platform incentivizes users to participate by providing them with a service. It also acts as an aggregator, collecting data from participating users and selling them downstream. Therefore, potential users face the following trade-off - do they abstain from joining and miss out on the utility provided by the platform, or incur privacy costs by participating and sharing their data ?

In light of the rapidly changing privacy attitudes of users towards online platforms, we introduce a novel modeling element for such two-sided markets: the privacy costs of participating users in our model are ***endogenous*** and depend on ***how many downstream buyers gain access to their data.*** Our main contributions are the following: i) providing a complete characterization of marketplace equilibria for two classes of user utility functions (when each user gets a fixed utility from participating, and when the utility is linearly increasing in the number of other users that participate) and ii) providing a comparative analysis with the setting where privacy costs are exogenous and fixed. We demonstrate that market equilibria change significantly when endogeneity in user privacy costs are accounted for. Finally, we conclude by providing simulations and semi-synthetic experiments that extend our results to more general assumptions. In particular, we experiment with different distributions of user privacy costs and different functional forms of user utilities.

2 - Repeated Contracting with Multiple Non-Myopic Agents: Policy Regret and Limited Liability

Varun Gupta, University of Pennsylvania, Philadelphia, PA, United States, Natalie Collina, Aaron Roth

We study a repeated contracting setting in which a Principal adaptively chooses amongst k Agents at each of T rounds. The Agents are non-myopic, and so a mechanism for the Principal induces a T-round extensive form game amongst the Agents. We give several results aimed at understanding an under-explored aspect of contract theory -- the game induced when choosing an Agent to contract with. First, we show that this game admits a pure-strategy \emph{non-responsive} equilibrium amongst the Agents -- informally an equilibrium in which the Agent's actions depend on the history of realized states of nature, but not on the history of other's actions. Next, we show that if the Principal selects Agents using a \emph{monotone} bandit algorithm, then for any concave contract, in any such equilibrium, the Principal obtains no regret to contracting with the best Agent in hindsight -- not just given their realized actions, but also to the counterfactual world in which they had offered a guaranteed T-round contract to the best Agent in hindsight, which would have induced a different sequence of actions. Finally, we show that if the Principal selects Agents using a monotone bandit algorithm which guarantees no swap-regret, then the Principal can additionally offer only limited liability contracts (in which the Agent never needs to pay the Principal) while getting no-regret to the counterfactual world in which she offered a linear contract to the best Agent in hindsight -- despite the fact that linear contracts are not limited liability.

3 - Bayesian Strategic Classification

Saeed Sharifi-Malvajerdi, Toyota Technological Institute at Chicago, Chicago, IL, United States, Lee Cohen, Kevin Stangl, Ali Vakilian, Juba Ziani

In strategic classification, agents modify their features, at a cost, to obtain a positive classification outcome from the learner’s classifier, typically assuming agents have full knowledge of the deployed classifier. In contrast, we consider a Bayesian setting where agents have a common distributional prior on the classifier being used and agents manipulate their features to maximize their expected utility according to this prior.

The learner can reveal truthful, yet not necessarily complete, information about the classifier to the agents, aiming to release just enough information to shape the agents' behavior and thus maximize accuracy. We show that partial information release can counter-intuitively benefit the learner's accuracy, allowing qualified agents to pass the classifier while preventing unqualified agents from doing so.

Despite the intractability of computing the best response of an agent in the general case, we provide oracle-efficient algorithms for scenarios where the learner's hypothesis class consists of low-dimensional linear classifiers or when the agents' cost function satisfies a sub-modularity condition. Additionally, we address the learner's optimization problem, offering both positive and negative results on determining the optimal information release to maximize expected accuracy, particularly in settings where an agent's qualification can be represented by a real-valued number.

4 - The Hidden Costs of Privacy Choice for Marginalized Groups

Tamalika Mukherjee, Columbia University, New York, NY, United States, Rachel Cummings, Talia Gillis

In both the U.S. and Europe, efforts to regulate privacy concerns often rely on a `notice and consent' approach. Under this approach, organizations are required to provide clear and understandable notices to users about their data practices, including what information is being collected, how it is being used, and with whom it is being shared. Users are then given the opportunity to consent to these practices. While there is a rich literature that studies the potential harms caused by individuals giving consent (in the context of privacy notices) and the role of consent itself in shaping privacy policies, little attention has been paid to the negative impact of choice on marginalized groups, i.e., the consequences of individuals from marginalized groups withholding consent. When the collection and usage of information provides for some group benefits, the individual's decision to withhold information can create information externalities. We consider situations in which the negative externalities resulting from the withholding of personal information disproportionately impact marginalized groups,and develop a mathematical framework that encapsulates these harms.

5 - You Can Have Your Cake and Redistrict It too

Jamie Tucker-Foltz, Harvard University, Allston, MA, United States, Gerdus Benade, Ariel Procaccia

The design of algorithms for political redistricting generally takes one of two approaches: optimize an objective such as compactness or, drawing on fair division, construct a protocol whose outcomes guarantee partisan fairness. We aim to have the best of both worlds by optimizing an objective subject to a binary fairness constraint. As the fairness constraint we adopt the geometric target, requiring the number of seats won by each party to be at least the average of its outcomes under its worst and best possible partitions of the state.

To study the feasibility of this approach, we introduce a new model of redistricting, closely mirroring the classic model of cake-cutting. This model has two innovative features. First, in any part of the state there is an underlying "density" of voters with political leanings toward any given party, making it impossible to finely separate voters for different parties into different districts. Second, parties may disagree on the distribution of voters. In the absence of a "ground truth" distribution, a redistricting algorithm must therefore aim to simultaneously be fair to each party with respect to its own reported data. Our main theoretical result is that, surprisingly, the geometric target is always feasible with respect to arbitrarily diverging datasets on how voters are distributed.

Our empirical results, which use real election data and maps of six US states, demonstrate that the geometric target is always feasible, and that imposing it as a fairness constraint comes at almost no cost to three well-studied optimization objectives.

Summit - 330

Enhancing Health Outcomes and Performance Through Integration and Analysis

Contributed Session

Chair: Yoon Sang Lee, Columbus State University, Columbus, GA, United States

1 - Controlled Under-Sampling with Stacking Ensemble Learning for Class Imbalance Problem

Yoon Sang Lee, Columbus State University, Columbus, GA, United States, Riyaz Sikora

Imbalanced data sets are a growing problem in data mining and business analytics. However, their ability to predict the minority class deteriorates in the presence of class imbalance. Although there have been many approaches that have been studied in literature to tackle the imbalance problem, most of these approaches have been met with limited success. In this study, we propose three methods based on a wrapper approach by combining the use of under-sampling with ensemble learning to improve the performance of standard data mining algorithms. We test our ensemble methods on 10 data sets collected from the UCI repository with an imbalance ratio of at least 70%. We compare their performance with two other traditional techniques for dealing with the imbalance problem and show significant improvement in the recall, AUROC, and the average of precision and recall.

2 - Wealth Shocks and Physician Behavior: Evidence from Childbirth

Yanhao Wang, Indiana University Bloomington, Bloomington, IN, United States

Little is known about how physicians' personal wealth affects their behavior. Using data on physicians' housing returns linked to their treatment choices, this paper provides new empirical evidence on the sensitivity of physicians' behavior to their wealth and studies the policy implications on medical expenditure and patient health. Specifically, I look at obstetricians who have large discretion and significant financial incentives in choosing cesarean sections over vaginal deliveries. For identification, I rely on the variation in obstetricians' housing returns arising from the Great Recession, depending on when or where they purchased their houses ex-ante. Using a patient-level regression model with obstetrician fixed effects, I estimate that a one-standard-deviation decrease in obstetricians' housing wealth leads to an increase of 1.8 percentage points, or 4.5%, in C-section probability. The increased C-section rate leads to longer in-hospital stays and higher infection rates among the patients. Finally, I show in two counterfactuals that the estimated wealth sensitivity is useful in predicting the effectiveness of price regulations and alternative payment models.

3 - Racial Disparities and Comorbidities: Network Analysis of Maternal Outcomes in Alabama

Yasin Fatemi, Auburn University, Auburn, AL, United States, Haneen Ali, Jingyi Zheng

Introduction The study employed a robust network analysis methodology to assess the effects of race and comorbidities on birth outcomes, using a dataset of 443,902 mothers in Alabama from 2014 to 2021.

Methods Four multimorbidity networks corresponding to White, Black American, Asian, and American Indian or Alaskan Native groups were constructed to explore distinct comorbidity patterns. The nodes in these networks represented various diseases, while the edges, quantified by the Salton Cosine Index, depicted the associations between these conditions. Additionally, two separate networks were analyzed for low birth weight (LBW) and normal birth weight (NBW) to identify the differential impacts of specific diseases. Feature selection methods including Random Forest and Logistic Regression were applied to pinpoint crucial intersections between the LBW and NBW networks, enhancing the granularity of the analysis.

Results The findings indicated significant racial disparities in the density of comorbidity networks, with more complex disease interactions observed among Black, Indian, and Asian groups compared to Whites. Preexisting hypertension and eclampsia emerged as significant risk factors for LBW in White and Black groups, while gestational hypertension was prevalent across multiple racial groups. The LBW network displayed greater density than the NBW network, highlighting the intricate connections between comorbidities leading to adverse birth outcomes.

Conclusion These insights underline the necessity for healthcare interventions tailored to the distinct health profiles of each racial group to effectively address and reduce maternal health disparities.

4 - Assocation between Medicaid policy regarding dental benefits and tooth retention

Marta Ventura, Penn State University, University Park, PA, United States, Paul Griffin

Extensive tooth loss affects function, general health, and quality of life. The World Health Organization considers retaining 20 natural teeth as necessary for functional dentition. Increasing access to clinical dental care among adults could significantly reduce tooth loss. The two most common diseases that cause tooth loss, such as dental caries and periodontal disease. We use a binomial ordinal logistic regression to examine the association between Medicaid policy regarding dental benefits and tooth retention. For this model, the exposure variable is based on whether person had continuous Medicaid exposure from 2007 to 2012 and from 2013 to 2018. The data that we used came from the Centers for Disease Control and Prevention (CDC) survey called Behavioral Risk Factor Surveillance System (BRFSS). The BRFSS includes one question on the number of teeth lost due to tooth decay or gum disease. We used the response to this question to develop two categories of tooth retention: functional dentition (0 to 5 missing teeth) and not having functional dentition (6 or more missing teeth). This model accounts for change in 'Comprehensive Benefits' over time; and uses high-income (Non-Medicaid) as a control. The study population are adults 35 years old - 54 years old. The 'exposure' is 1) no benefits in *either* period 2007-2012 and 2013- 2018; 2) continuous benefits in *both* periods 2007-2012 and 2013- 2018; 3) *no* benefits in 2007-2012 and *benefits* in 2013-2018 (meaning they *gained* benefits); and 4) *benefits* in 2007-2012 and *no* benefits in 2013-2018 (meaning they *lost* benefits).

Summit - 331

Operational Planning of Emerging Vehicle Technologies

Contributed Session

Chair: Heeseok Moon, Kyunghee University

1 - Solving optimal relocation transport problem in shared mobility services

JOON MOON, The Ohio state university, Columbus, OH, United States, Qadeer Ahmed

The rise of micromobility sharing services such as scooters and bike sharing, exemplified by companies like Lime and Uber, has led to significant global demand for shared mobility. However, these services often struggle with supply-demand imbalances, particularly in locations and times where there is an excess of supply or demand. Therefore, relocating vehicles, often conducted overnight, is crucial to ensure optimal service coverage. This paper delves into the problem of vehicle relocation in shared mobility services to minimize transport costs. To solve this problem, this study proposes a problem formulation and approach that is grounded in the optimal transport theory. When comparing the conventional assignment problem formulation, which treats each demand and supply as separate entities and can be deterministic and computationally burdensome, the optimal transport formulation is expected to simplify large-scale problems while maintaining its utility. We highlight the effectiveness of our proposed approach in comparison to conventional methods based on the mathematical formulation of assignment problems. Additionally, these methodologies are validated using data from a bike-sharing service in Seoul, South Korea, providing practical insights into effective relocation strategies for addressing clustered demand and supply challenges.

2 - An enhanced adaptive large neighborhood search procedure for a rich vehicle routing problem

Gizem Ozbaygin, Sabanci University, Istanbul, Turkey, Saeedeh Ahmadi Basir

Motivated by a real-life application, this study focuses on a rich vehicle routing problem characterized by a multi-period planning horizon, time window constraints, visual attractiveness and driver consistency concerns. We propose an enhanced adaptive large neighborhood search procedure to tackle the problem and report our findings based on computational experiments.

3 - Decision Support Framework in Electric Vehicle Charging Technologies Using Patent Data: A Multi-criteria Approach Considering National Technology Portfolio, Technology Impact and Development Stage

Heeseok Moon, Kyunghee University, Seoul, Korea, Republic of, Hyunhong Choi

In the context of global efforts towards carbon neutrality and climate change response, the strategic importance of charging technologies for expanding electric vehicle (EV) deployment is increasingly recognized. This study identifies 40 potential technology topics using Structural Topic Model (STM) on 10,393 patent data related to EV charging technology over 12 years (2010-2021) collected by the USPTO. The correlation between these topics reveals seven clusters with distinct technological properties. Based on this, a comprehensive comparison of the technology portfolios of six major countries (US, Japan, France, Germany, Korea, China) was conducted, highlighting each country's strengths and strategic focus areas. Emerging technologies were identified through patent application year and citation data, providing an overview of the EV charging technology landscape.

To develop a comprehensive decision-making framework, technologies were classified into embryonic, growth, and maturity stages through a technology life cycle assessment. This framework utilized country-specific technology focus and topic influence to present suitable strategies for each country. This study not only provides a comprehensive overview of global technology development trends but also serves as an essential tool for investment support and policy development, aiding in the establishment of customized industrial strategies. Furthermore, it supports the sustainable expansion of EV charging infrastructure.

This research makes three key contributions: it conducts the first patent analysis of EV charging technologies, provides visualized results for policymakers through technology cluster analysis and national technology portfolio comparisons, and proposes an effective screening tool for national R&D investment by introducing the concept of the technology life cycle

TC12

Summit - 332

Intermodal and Sustainable Freight Logistics

Contributed Session

Chair: Hyunseop Uhm, Argonne National Laboratory, Lemont, IL, United States

1 - Intermodal Inbound Freight Allocation Optimization for Port-Hinterland Distribution Planning

Sarita Rattanakunuprakarn, University of Tennessee, Knoxville, Knoxville, TN, United States, Mingzhou Jin

Improving freight distribution between ports and hinterlands is essential for optimizing transportation networks. This research introduces an innovative approach for optimizing inbound freight allocation and facility location selection within the port-hinterland distribution framework of the U.S. Southwest region, specifically emphasizing the network originating from the San Pedro Bay port complex. By utilizing a Stochastic Mixed Integer Programming (MIP) model, our approach allocates goods for transportation via railroads and trucks, while also considering the availability of distribution centers. Unlike traditional practice that primarily rely on port proximity, our proposed network integrates hinterland distribution centers into the logistical framework, thereby refining container classification and unit-train formation processes. The model evaluates performance based on transportation efficiency and cost-effectiveness, taking into account economic, environmental, and social factors. This study contributes to the advancement of freight distribution strategies, thereby enhancing the resilience and sustainability of port-hinterland logistics networks.

2 - Sustainable collaborative urban supply chains (STRAUSS): A comparative study for waste collection

Dilay Aktas, KU Leuven Institute for Mobility, Leuven, Belgium, Pieter Vansteenwegen

In the STRAUSS project, we develop mathematical models and algorithms to optimize urban logistics operations. Unlike existing studies, STRAUSS specifically targets the urban context and considers the measures implemented by city administrations that impact logistics operations within their territory. These measures may include car-free zones, designated parking spaces or time windows for truck deliveries, and bans on certain vehicles in specific areas. Our algorithms evaluate the impact of these measures to mitigate the negative effects of logistics operations on city livability and enhance the competitiveness of supply chain actors. Contrary to existing urban logistics optimization problems, our models are grounded in an in-depth economic analysis. This work focuses on one crucial stream of daily logistics operations: waste collection. Typically, waste collection trucks enter the city empty to collect waste, while delivery trucks from supply chain actors return empty to their depots. Consequently, trucks are on average only half-full during their transportation routes. We explore the integration of deliveries to retail stores in the city center with waste collection, examining how this scheme could be practically implemented and identifying potential drawbacks. We develop a routing-optimization model to generate combined collection-and-delivery routes and evaluate these scenarios using a case study.

3 - Advanced Multimodal Urban Transport: Synchronizing Freight Delivery and Passenger Movement

Nastaran Tork, University of Minnesota, Minneapolis, MN, United States, Chengwenjian Wang, Alireza Khani, Jean-Philippe Richard

Urban congestion and pollution are critical challenges demanding innovative, interconnected transportation solutions. This study proposes an integration of freight delivery into the light-rail transit network, optimizing the system to accommodate both passengers and parcels. The approach involves the use of strategically placed lockers at train stations where parcels can be dropped off by first-mile services or customers and then delivered to destination lockers via trains. The core objective is to create a decision-support framework that adaptively distributes and routes parcels and minimize total delivery time, costs and number of selected stations and crowd-shipping services adapted for freight transportation. This framework incorporates various uncertainties, including fluctuating parcel volumes, specific delivery time requirements, and last-mile logistics constraints. It also considers the dynamic availability of train capacity, considering both current and predicted passenger numbers. These variables are modeled through a range of scenarios to ensure flexibility. We propose a stochastic optimization model for dynamic routing, enhanced by predictive analytics for accurate demand forecasting. We discuss the formulation of the model, including the key constraints and objectives, as well as the methods used to solve it. Computational results on a case study from a major city are presented to demonstrate the practical applicability and benefits of the approach.

4 - Implementation and Analysis of Urban Freight Electrification for the E-commerce Delivery using POLARIS Transportation Framework

Hyunseop Uhm, Argonne National Laboratory, Lemont, IL, United States, Abdelrahman Ismael, Natalia Zuniga-Garcia, Olcay Sahin, James Cook, Joshua Auld, Monique Stinson

Freight truck electrification for last-mile delivery is one of the most important research topics to reduce the dependency on fossil fuel operations. Although a battery electric truck still has limitations on daily operations with lower driving ranges and higher purchasing cost than a conventional truck, operations with electrified trucks reduce total energy usage and recharging/refueling cost. In this paper, we develop and implement a fleet-mix and multi-shift e-commerce delivery model into POLARIS, an agent-based transportation modeling framework. Based on the e-commerce delivery orders synthesized by POLARIS demand model, a fleet owner decides the best electrification ratio of the fleet and the proper number of chargers which gives the minimum total cost. The initial truck operation planning is described as mixed-integer linear programming model including common constraints for heterogeneous vehicle routing problem, multi-shift operation with recharging scheduling, and recharger allocation. A bi-level VNS-TS heuristic with the event trigging and memory managing features in POLARIS is also suggested for efficient solution search. All truck tours for daily e-commerce delivery are simulated onto the POLARIS transportation network with other passenger travel, energy use and battery level of every truck is tracked at every simulation timestep, and route replanning and en-route recharging models are added to modify the initial plan for the route feasibility. Finally, the best EV ratio with different EV driving ranges, recharging/refueling cost, and public recharger availability scenarios are evaluated in multiple POLARIS metropolitan cities.

Summit - 333

Circular Economy and Sustainable Supply Chains

Contributed Session

Chair: Geng Deng, Harbin Engineering University, Harbin, N/A

1 - Managerial Efficiency and Ordering Policies in a Circular Economy

Sergey Naumov, Smeal College of Business, The Pennsylvania State University, University Park, PA, United States, Saurabh Bansal, V Daniel R Guide

A Circular Economy (CE) is a system where products are collected after customers have used them, remanufactured, and then put back in circulation for further use. This reduces the need for virgin materials to manufacture new units and wastage from used units. However, it is well-known that delays in inventory returns often lead managers to make suboptimal ordering decisions. This problem is important in CE systems, where poor inventory management can reduce or completely negate CE benefits, but existing literature lacks evidence on its magnitude and key contributing factors. Addressing this gap is essential for developing operational details and maximizing benefits of CE systems. Using a novel complexity ordering, we investigate the quality of managerial decision-making. In our experimental study, participants made inventory replenishment decisions in various CE systems that differed in the complexity of reverse-flow of goods. We find that participants' operating costs were three to five times higher than normative costs, and, as CE system became more complex in reverse-flow, the suboptimality of managerial decision-making worsened. Our experimental results provide prescriptions and guidance for practitioners by identifying: (i) CE configurations for which managerial decision-making tends to be better, and (ii) behavioral nudges to improve the quality of decision-making.

2 - Location-Routing Strategies for Drug Take-Back Programs in Rural Area

Jihyun Jo, National Institute of Standards and Technology, Gaithersburg, MD, United States, Evan Wallace

The circular economy is a sustainable model that emphasizes sharing, leasing, reusing, repairing, refurbishing, and recycling existing materials and products. One of aims is protecting environment by minimizing waste. Despite the pharmaceutical industry's significant contribution to global health, it is a major source of river water pollution. Pharmaceutical waste, including drugs and metabolites, enters river through improper disposal practices. Waste is generated throughout the pharmaceutical supply chain due to factors such as overproduction, excess stocks, improper storages, and overprescription, etc. In the United States, drug take-back program and state prescription drug repository programs are implemented, and these programs reduce the pharmaceutical waste. However, they face challenges, including the availability of drop-off locations, which vary by region and are often limited in rural areas compared to urban areas. To address this challenge, we propose a location-routing model specifically tailored for rural areas. We consider two heuristics: one that prioritizes determining drop-off locations before planning individual routes using the multi-depot vehicle routing problem, and another that plans individual routes first and then identifies suitable drop-off locations. Throughout the location-finding process for the second heuristic, we continuously optimize individual routes to enhance the overall solution.

3 - Does Corporate Cooperation Culture Foster Supply Chain Resilience? A Large-Scale Empirical Study

Deng Geng, Harbin Engineering University, Harbin, China, People's Republic of, Liu Weiwei, Lee Ruby

Despite firms' efforts to maintain their supply chains in complex business environments, they are now more vulnerable to supply chain disruptions than ever before and have begun to pay attention to how to enhance resilience against such disruptions. The existing literature has limited attention on how corporate cooperation culture affects supply chain resilience, and large-scale empirical evidence capturing the complex relationship between corporate cooperation culture and supply chain resilience remains elusive. Our research begins to bridge this gap by adopting a textual analysis approach to construct metrics for measuring corporate cooperation culture and examining its interplay with

supply chain resilience. Based on empirical testing of data from 4751 Chinese listed companies, we found that corporate cooperation culture is positively correlated with supply chain resilience. Further research revealed that supply chain transparency plays a mediating role, and corporate ESG disclosure partially moderates the impact on supply chain resilience. These findings significantly expand the literature on supply chain resilience and contribute to a better understanding of the comprehensive impact of corporate cooperation culture on supply chain resilience.

Financial Decision Making and Risk Management

Invited Session

Finance

Chair: Dohyun Ahn, CUHK, Shatin, Hong Kong

1 - Dynamic Pricing in Equity Crowdfunding: Optimizing Success in Blockchain Ventures

Bretislav Hajek, National University of Singapore, Singapore, Singapore, Jussi Keppo, Steven Kou

Equity crowdfunding has become a favored method for blockchain-based companies to raise initial capital by offering governance tokens as equity. This model enables real-time price and marketing adjustments in response to demand, bypassing the need for an investment bank typically required for an IPO. Our research models equity crowdfunding as a continuous-time problem, examining its optimal pricing strategy. We demonstrate that dynamic pricing increases fundraising effectiveness and the success rate of crowdfunding campaigns. Furthermore, we assess the moral hazard associated with this approach and investigate the potential advantages for investors.

2 - (Almost) Model-Free Dynamic Mean Quadratic Variation Analysis of Log Returns

Chihoon Lee, Stevens Institute of Technology, Hoboken, NJ, United States, Zhenyu Cui, Dongwoo Kim, Yanchu Liu

In this paper, we propose an almost model free dynamic mean quadratic variation (MQV) asset allocation analysis for log returns, which is named log-MQV. It has several advantages, including recovering the time-consistency in the optimal investment decision, conforming to investment wisdom, and the explicit closed-form optimal investment decisions for most stochastic models in finance under both complete and incomplete market settings. The proposed model covers multivariate Ito diffusion models, and can further incorporate jump risks, regime switching and stochastic volatility features through a unified framework. We also illustrate that the proposed framework allows for a fully data-driven implementation utilizing historical time series data, and this paves the path for a fully data-driven robo-advising investment strategy. Extensive numerical and empirical experiments illustrate the performance of the proposed optimal log-MQV portfolio.

3 - Robust Optimal Strategies for Two-Period Liquidation in Financial Systems

Hongyi Jiang, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong, Dohyun Ahn

We study the problem of two-period liquidation strategies in financial systems. During financial crises, asset liquidation is often inevitable but can lead to substantial losses if a significant amount of assets are sold simultaneously at depressed prices. To tackle this challenge, we consider a two-period liquidation model that allows for preemptive liquidation before maturity and propose a worst-case approach to the associated liquidation problem. Specifically, we propose a tractable liquidation strategy that maximizes a bank's worst-case cash position after liquidation, taking into account the uncertainty of other banks' liquidation decisions. In addition, we find that the unique Nash equilibrium is attained when all banks adopt this proposed strategy. We further demonstrate that the worst-case optimal strategy retains a similar form even when interbank liabilities are involved, where we consider both scenarios of full network information and partial network information. While our analysis builds upon a stylized model, our findings offer valuable guidelines for developing robust liquidation strategies that mitigate losses resulting from asset liquidation.

4 - Stressed Distribution Selection via Causal Optimal Transport

Eunji Kwon, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of, Kyoung-Kuk Kim

Recently, causal optimal transport has emerged as an alternative to classical optimal transport for capturing a temporal information structure between probability distributions within their Wasserstein distance. Utilizing this framework, we focus on identifying a stressed distribution with minimal transportation cost. We demonstrate primal attainment and present a dual reformulation incorporating entropic regularization, establishing the strong duality. This reformulation facilitates the computation of optimal solution to our problem.

Revenue Management and Pricing

Chair: Ruihao Zhu, Cornell University, Ithaca, NY, United States

1 - Pricing Analytics of Primary and Ancillary Products Using Conversion Rate Data

Changchun Liu, National University of Singapore, Singapre, Singapore, Hailong Sun, Chung Piaw Teo, Maoqi Liu

This paper focuses on a firm that sells both primary and ancillary products to customers, with the condition that customers can purchase the ancillary products only if they purchase the primary ones. Our goal is to jointly determine the prices for all the products to optimize profits to the firm. This problem is challenging as it involves customer choice over subsets (primary product + ancillary services) and precedence constraints on purchase decisions. To tackle these challenges, we use a class of additive perturbed utility model (APUM) to explicitly capture the complex customer choice scenarios. We show that the ground-truth choice model can be uniformly approximated by an APUM under suitable reformulation. To facilitate the model calibration, we construct a tractable APUM by introducing slack variables of the choice constraints. In particular, we leverage the separable structure of APUM and design a polynomial number of price experiments to obtain market share shift information, which allows us to calibrate the APUM model with shape constraints. By utilizing piecewise linear approximation, we demonstrate that the resulting data-driven pricing problem can be formulated as a mixed integer program, which can be efficiently solved by commercial solvers. Through extensive numerical experiments, we provide compelling evidence of the superior performance of our framework compared to other methods. This opens up a new way to solve the ancillary pricing problem (and potentially other multidimensional pricing problems under complex customer choice behavior) in a data-driven manner.

2 - Two-stage Online Reusable Resource Allocation: Advance Reservation, Overbooking and Confirmation Call

Ruicheng Ao, Massachusetts Institute of Technology, Cambridge, MA, United States, Hengyu Fu, David Simchi-Levi

We investigate an online reusable resource allocation problem with advance reservations, modeling it as a two-stage admission control problem. In Stage I, customer requests arrive randomly over time at a nonstationary rate to reserve one unit of capacity for a random duration. The number of accepted reservations may exceed the available capacity, a practice known as overbooking. In Stage II, both customers with reservations and walk-in customers arrive to check in sequentially. Reservations for day k can be canceled by customers without penalty before the confirmation call, which is made by the decision maker (DM) at some time before the day's service ends. The DM must make admissions decision upon receiving booking requests or check-ins. If a check-in from a reservation is rejected, an overbooking loss occurs. Our objective is to develop an online admission control policy that maximizes expected total revenue. We propose a dynamic thresholding policy that achieves constant regret compared to the optimal offline policy. Furthermore, we demonstrate that, with a logarithmically smaller scale of walk-in customers, no online policy can achieve better regret than Ω(T). We make a sensitivity analysis on the confirmation time, revealing that the DM can delay confirmation until a small logarithmic interval before the end of the day while still achieving near-optimal performance. Additionally, we conduct numerical experiments to examine the relationships between reservation and walk-in arrival rates, the confirmation time, and the performance of our proposed algorithm.

3 - Endogenous State Transitions in Transfer Learning and Dynamic Pricing

Shiyuan Wang, Tsinghua University, Beijing, China, People's Republic of, Jing-Sheng Song, Bora Keskin

This paper studies transfer learning in the context of dynamic pricing and endogenous state transitions. We consider a seller offering a large number of related products that are sold sequentially, each over a discrete time horizon. The expected demand for a product is a function of the product's price and a state variable that depends on past product prices. For each product, the parameters of the demand function are drawn from a common distribution based on the state variable. The seller does not know the underlying demand parameters and needs to learn them from accumulating noisy demand observations. The salient feature of our study is the endogenous state transitions: the state variable characterizes the key uncertainty in each product's pricing problem, and the state transition from one product to the next depends on previous pricing decisions. We develop an algorithm that simultaneously learns the common distribution and the demand parameters for each product to maximize cumulative revenue. We also establish an upper bound on the regret of our algorithm as well as a matching lower bound on regret, which implies that our algorithm is rate-optimal. Numerical experiments demonstrate our algorithm's good performance.

4 - Satisficing Exploration in Bandit Optimization

Qing Feng, Cornell Tech, New York, NY, United States, Tianyi Ma, Ruihao Zhu

Motivated by the concept of satisficing in decision-making, we consider the problem of satisficing exploration in bandit optimization. In this setting, the learner aims at finding a satisficing arm whose mean reward exceeds a certain threshold. The performance is measured by satisficing regret, which is the cumulative deficit of the chosen arm's mean reward compared to the threshold. We propose SELECT, a general algorithmic template for Satisficing Exploration via LowEr Confidence bound Testing, that attains constant satisficing regret for a wide varieties of bandit problems even when the arm space is large and possibly infinite (whenever a satisficing arm exists). Specifically, given a class of bandit optimization problems and a corresponding (standard) regret minimization oracle, SELECT iteratively makes use of the oracle to identify a potential satisficing arm. Then, it collects data samples from this arm, and continuously compares the lower confidence bound of the identified arm's mean reward against the threshold value to determine if it is a satisficing arm. As a complement, SELECT also enjoys the same (standard) regret guarantee as the oracle whenever no satisficing arm exists. Finally, we conduct numerical experiments to validate the performance of SELECT for several popular bandit optimization settings.

5 - Near-Optimal Policies for CMDP with Applications in RM

Jiashuo Jiang, Hong Kong University of Science and Technology, Hong Kong, China, People's Republic of

Constrained Markov Decision Process has been a popular framework for online decision making. In this problem, the decision maker interacts with an unknown environment, where the state of the environment evolves in a Markovian manner. The goal of the decision maker is to maximize the total accumulated reward subject to some long-term constraints. It finds recent applications in modeling resource allocation problems. In this talk, I will present a recent advance in the study of the learning problem for CMDP. The main result is an instance-dependent $\tilde{O}(1/\epsilon)$ sample complexity for approximating the optimal policy. Several new elements are introduced to achieve this improved result, including i) a LP basis characterization of instance hardness, ii). a modified resolving heuristics with a stablized optimal basis. This is based on a joint work with Yinyu Ye.

Advances in Revenue Management

Invited Session

Revenue Management and Pricing

Chair: Omar Mouchtaki, New York University, New York, NY, United States

Co-Chair: Pnina Feldman, Darden School of Business, UVA, Charlottesville, VA, United States

1 - Interpolating Item and User Fairness In Multi-Sided Recommendations

Qinyi Chen, Massachusetts Institute of Technology, Cambridge, MA, United States, Jason Cheuk Nam Liang, Negin Golrezaei, Djallel Bouneffouf

Today's online platforms rely heavily on algorithmic recommendations to bolster user engagement and drive revenue. However, such algorithmic recommendations can impact diverse stakeholders involved, namely the platform, items (seller), and users (customers), each with their unique objectives. In such multi-sided platforms, finding an appropriate middle ground becomes a complex operational challenge. Motivated by this, we formulate a novel fair recommendation framework, called Problem (FAIR), that not only maximizes the platform's revenue, but also accommodates varying fairness considerations from the perspectives of items and users. Our framework's distinguishing trait lies in its flexibility: it allows the platform to specify any definitions of item/user fairness that are deemed appropriate, as well as decide the "price of fairness" it is willing to pay to ensure fairness for other stakeholders. We further examine Problem (FAIR) in a dynamic online setting, where the platform needs to learn user data and generate fair recommendations simultaneously in real time, which are two tasks that are often at odds. In face of this additional challenge, we devise a low-regret online recommendation algorithm, called FORM, that effectively balances the act of learning and performing fair recommendation. Our theoretical analysis confirms that FORM proficiently maintains the platform's revenue, while ensuring desired levels of fairness for both items and users. Finally, we demonstrate the efficacy of our framework and method via several case studies on real-world data.

2 - Assortment Optimization for General Multi-Purchase Choice Models

Wenhao Gu, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Anton Braverman, Tarek Abdallah

The static assortment optimization problem is a classical and well-studied problem where customers choose a single item while behaving according to some customer choice model like the ubiquitous random utility model. However, the variant where customers purchase multiple items has received less attention, primarily due to the added complexity of modeling utility-maximizing behavior over sets of items, even when considering natural extensions of the standard MNL choice model. In this paper, we propose a general multi-purchase choice model that can be viewed as a natural extension of the single-purchase utility choice models. We also study the respective assortment optimization problem without making specific distributional assumptions on the random utilities. We propose a computationally efficient algorithmic framework that is based on an asymptotic regime referred to as the large-offering regime, where the number of items available to the retailer grows large. Through this asymptotic lens, we develop an efficient approximation algorithm with corresponding asymptotic optimality guarantees under general utility distributions. Our numerical results demonstrate that our algorithm is very competitive even when the number of items available to the retailer is modest and even when the customers choose a single item.

3 - Rationality-Robust Information Design: Bayesian Persuasion Under Quantal Response

Wei Tang, Chinese University of Hong Kong, Hong Kong, Hong Kong, Yiding Feng, Chien-Ju Ho

Classic mechanism/information design imposes the assumption that agents are fully rational, meaning each of them always selects the action that maximizes her expected utility. Yet many empirical evidence suggests that human decisions may deviate from this full rationality assumption. In this work, we attempt to relax the full rationality assumption with bounded rationality. Specifically, we formulate the bounded rationality of an agent by adopting the quantal response model (McKelvey and Palfrey, 1995).

We develop a theory of rationality-robust information design in the canonical setting of Bayesian persuasion (Kamenica and Gentzkow, 2011) with binary receiver action. We first identify conditions under which the optimal signaling scheme structure for a fully rational receiver remains optimal or approximately optimal for a boundedly rational receiver. In practice, it might be costly for the designer to estimate the degree of the receiver's bounded rationality level. Motivated by this practical consideration, we then study the existence and construction of robust signaling schemes when there is uncertainty about the receiver's bounded rationality level.

4 - Too Good to Waste: Reducing Food Waste Through Markdown Platforms

Linghui Feng, Boston University, Boston, MA, United States, Pnina Feldman, Robert Swinney

This paper investigates the sustainability and efficiency of online food markdown platforms in reducing food waste. Despite established sustainability goals and efforts, significant quantities of food are still lost or wasted along the food supply chains. Several startups have developed a business model that sells surplus units from food retailers to consumers at discounted prices. Inspired by these companies, we analyze this markdown business through a stylized game-theoretical model, considering a revenue-sharing contract between a food markdown platform and a restaurant. By comparing this model with two benchmarks—no markdown and a centralized markdown approach—we find that while markdown platforms typically enhance profitability for restaurants over discarding food, they can lead to increased food waste under certain conditions. Additionally, we find that these platforms consistently perform better in reducing waste compared to the centralized markdown approach. Through a combination of analytical modeling and numerical simulations, we explore the trade-offs involved in these markdown strategies and propose an improved revenue-sharing contract to ensure sustainability. Further, in the extension of our base model, we investigate the impact of strategic consumer behaviors and market-clearing prices on restaurants' profitability and sustainability. We also discuss the potential of a government incentive program to mitigate these issues, proposing a practical design that could be implemented to realign market dynamics with environmental sustainability goals.

5 - A Modeling Framework for Tipping in the Presence of A Social Norm

Ran Snitkovsky, Tel Aviv University, Tel Aviv, Israel, Laurens Debo

Tipping is a complex phenomenon driven by social pressure, and cutting across various stakeholders -- firms, customers, and workers. Analyzing the long-run impact of policies related to tipping is therefore challenging. To facilitate such analysis, we develop a modeling framework, in which a tipping norm is formed endogenously in a market comprised of a price-setting firm offering service to potential customers. Customers choose whether to consume the service or not, and if yes, how much to tip the server afterwards. With tipping, customers show reciprocity to the server by sharing a fraction of their surplus, but also undergo social pressure to comply with the prevailing norm of tipping. This tipping norm is shown to evolve endogenously through a dynamic process of sequential market adjustments over time: the average tip
determines in each time period the tipping norm for the next period, causing the firm to adapt its price and customers to adapt their tips

accordingly. The average tip-to-price ratio converges (from below) to a stable market-equilibrium outcome. Characterization of this equilibrium outcome allows us to derive qualitative results about the long-run impact on tipping of different exogenous factors such as customers' sensitivity to social pressure and the quality of service. Building on this framework, we further investigate several economic implications of tipping pertaining social welfare, labor cost, and service quality, thus, uncovering incentives and trade-offs to which the tipping mechanism give rise, from the firm’s, the worker’s, and the customer’s perspectives.

Socially Responsible Supply Chains

Invited Session

MSOM: Supply Chain

Chair: Gizem Korpeoglu, TU/e, Eindhoven, 5632TE, Netherlands

Co-Chair: Sina Khorasani, Vanderbilt University, Franklin, TN, United States

1 - Mergers of Consumer Cooperatives

Cigdem Gizem Korpeoglu, TU/e, Eindhoven, Netherlands, Sina Khorasani

Consumer cooperatives are consumer-owned and managed enterprises that aim to achieve buyer power and maximize their members' welfare. Recently, several cooperatives in major economies, such as the UK and Italy, merged to increase their buyer power and achieve lower prices for their members. We seek to understand how these mergers affect strategic interactions among supply chain players, market outcomes, and consumer welfare. We consider two-tier supply chains where multiple consumer cooperatives procure from a market for their member consumers. Multiple suppliers produce for this market and can increase their supplies by incurring scale-up costs. We show that mergers of cooperatives reduce prices, as intended. This enables consumers to allocate more of their income to purchasing other goods. However, lower prices also induce suppliers to reduce their production quantities, thereby causing each consumer to receive less of the supplied product. We find that this underproduction is even more pronounced in industries with low production scale-up costs. Due to this tradeoff between lower prices and underproduction, mergers of cooperatives make a nuanced impact on consumer welfare. We show, interestingly, that mergers harm both member and non-member consumers when the pre-merger number of cooperatives or scale-up cost is below a certain threshold. Otherwise, mergers benefit all consumers. We expand our results by considering horizontal and vertical differentiation among cooperatives and show that our results are robust and that differentiation increases the benefit of mergers. Policymakers should maintain healthy competition among cooperatives to maximize consumer welfare, especially in markets with low production scale-up costs.

2 - Supplier-Initiated and Buyer-Imposed Social Responsibility Codes of Conduct

Sriram Narayanan, Michigan State University, East Lansing, MI, United States, Han Zhang, Fei Gao, Mevan Jayasinghe

Buyer-imposed social responsibility codes of conduct have led to limited improvement in the social responsibility practices of suppliers. In response supplier-initiated voluntary codes of conduct have been increasingly accepted. We study a supplier’s decision on whether to adopt a voluntary code and a buyer’s decision on whether to impose its own code. We find that the stringency of the voluntary code determines whether it can effectively signal social responsibility. When the voluntary code signals ineffectively the buyer may impose its own code. Indeed the buyer may impose its code on a supplier that has adopted the voluntary code yet refrain from imposing its code on a supplier without any code. The strategy creates two distinct classes of suppliers: premium and economical. In general the voluntary code is not a substitute for the buyer’s code: the buyer may scrutinize a supplier more closely when the supplier has adopted the voluntary code. When the buyer incurs a low cost for the publicity of a supplier violation, increasing the stringency of the voluntary code will dampen supplier adoption of the code and loosen monitoring by the buyer at the same time, potentially increasing the likelihood of a violation slipping through detection.

Keywords: supplier code of conduct, social responsibility, signaling game, asymmetric information

3 - The Value of Negative Self-Disclosure in Supply Chain Social Responsibility

Tao Lu, University of Connecticut, Storrs, CT, United States, Yang Tong, Shi Chen

Some firms self-disclose social responsibility (SR) violations discovered in their supply chains. Motivated by this fact, we develop a game-theoretical model to explore the potential benefit of self-reporting negative SR incidences. We consider a buyer sourcing from an existing supplier and an incoming supplier. The buyer can be of high or low SR type, which is asymmetric information to the incoming supplier. First, the buyer audits the existing supplier, and if a violation is discovered, decides whether to disclose the violation. Then, the buyer audits the incoming supplier, whereas the incoming supplier chooses an SR effort to qualify for the buyer’s supply base. We show that through negative disclosure, a high-type buyer can effectively signal its ethical level to the incoming supplier, and such a separating equilibrium occurs if and only if the audit cost is within a medium range. Our results provide insights into how the audit cost and accuracy and the cost of negative disclosure influence an ethical firm's self-disclosure strategy and the SR violation risk in a supply chain.

4 - How Do Producers Fare with Fair Trade?

Ying Zhang, Santa Clara University, Santa Clara, CA, United States, Yen-Ting (Daniel) Lin, Adem Orsdemir, Heng Chen

Fair trade certificate promotes a sustainable livelihood for producers in developing countries. It ensures that producers are paid at a fair wage and potentially protects producers from the volatility in the commodity market. In this paper, we examine the impact of fair trade certificate on a fair trade retailer’s decisions, profitability and participating producers’ welfare. We also explore the impact of market size and proportion of myopic farmers on the optimal fair trade price that maximizes the producers' welfare. Furthermore, we investigate the disparity issue between myopic farmers and strategic farmers.

Emerging Technologies in Online Platforms

Invited Session

Revenue Management and Pricing

Chair: Bing Bai, McGill University, Montreal, QC, Canada

1 - Paying with TIME OR with Money: What Drives Customer Waiting Preferences?

Evgeny Kagan, Johns Hopkins Carey Business School, Baltimore, MD, United States, Andrew Davis, Kyle Hyndman

Many service offerings are characterized by two attributes: the price of the service and the time it takes to access or receive it. We experimentally study people’s preferences among time-money bundles. Participants in our experiments made repeated binary choices between two waiting formats: a short wait with a small monetary payoff, and a longer, potentially stochastic wait with a larger monetary payoff. We found that (1) certain waits are preferred to uncertain waits, though small amounts of uncertainty are ignored (2) there are no significant differences in how people evaluate ambiguous waits (where the probabilities of duration outcomes are unknown) compared to uncertain waits (where probabilities are known), (3) two-point waits (Bernoulli distribution) are preferred to continuous waits, while for continuous distributions, the upper bound may matter more than the variance and (4) people are most interested in receiving right-tail information about the duration of a wait, and most strongly respond to changes in the right tail.

2 - Digital Recommendations to Guide Cultural Experiences: Experimental Evidence at the Van Gogh Museum

Abhishek Deshmane, Georgia Institute of Technology, Atlanta, GA, United States, Ali Aouad, Victor Martínez de Albéniz

Technology interfaces and digital platforms play an increasingly vital role in mediating services and customers, offering relevant recommendations, context, and amplifying experiences. Through a field experiment conducted across the years 2022-2024, this study evaluates the impact of multimedia guide offerings at the Van Gogh Museum, focusing on visitor engagement, congestion, and educational objectives of the museum. Our findings aim to evaluate the effectiveness of such technology systems in cultural contexts by guiding visitors to specific exhibits, segmenting visitors based on their diverse needs and preferences, and addressing the challenges in estimating the marginal value of expanding tour offerings. Additionally, we explore the impact of visitor fatigue on the quality of the experience and propose leveraging experimental methods to optimize tour content for maximum audience engagement.

3 - The Value of Logistic Flexibility in E-Commerce

Bing Bai, McGill University, Montreal, QC, Canada, Tat Chan, Dennis Zhang, Fuqiang Zhang, Yujie Chen, Haoyuan Hu

In recent years, improving shipping speed in online retailing has faced significant diminishing marginal returns and significant cost increases. As a consequence, many online retailers have started to explore improving other aspects of the shipping experience to attract customers. In this paper, we use the introduction of local pick-up stations by Alibaba to study the impact of improving logistic flexibility on online retailing. We develop a choice model to study how logistic flexibility affects customers' purchase decisions. We find that customers value two types of logistic flexibility -- the value of time flexibility, which offers them the flexibility to receive their packages in their most preferred time; and the value of choice flexibility, which offers them the flexibility to make pick-up choices until the last minute to accommodate time uncertainty.

4 - Omnichannel Operations in on-Demand Delivery Platform with Buy-Online-and-Pick-up-in-Store

YU GUO, University of Science and Technology of China, Hefei, China, People's Republic of, Fei Gao, Wenchang Zhang, Liu Ming

On-demand delivery platforms now provide consumers with the option to buy online and pick up in-store (BOPS). We examine such an omnichannel on-demand economy, where consumers decide how their orders are delivered: by independent couriers or by themselves. First, we develop a stylized model to study the impact of BOPS on platform pricing strategies on both the courier and consumer sides. Our findings reveal new insights that differ from the delivery-only setting. After implementing BOPS, (i) the demand for delivery service decreases, yet the platform may increase price in the delivery channel; (ii) the platform ``recruits'' consumers to fulfill their own orders, but it may charge BOPS consumers an even higher price than for deliveries; (iii) surge pricing may no longer be optimal in response to a demand surge. Furthermore, the model is extended to incorporate a government-imposed wage floor. Although implementing BOPS reduces courier welfare, we show that policymakers may need to lower the wage floor to increase delivery opportunities for couriers. Finally, we estimate the model primitives using data from a leading meal-delivery platform in China and employ the estimated model to predict the impact of BOPS and wage regulations. We find that BOPS enhances platform profit by 12.00%, whereas it reduces labor welfare by 50.95%. Nevertheless, introducing wage floors alongside BOPS can improve labor welfare more effectively (up to +278.44%) compared to without BOPS (up to +220.14%). Moreover, with BOPS, a small wage floor can significantly increase labor welfare while causing minimal harm to the platform's profit.

5 - Optimal Subsidy Design: Application to Staple Food Subsidy

Zhicong Hu, London Business School, London, United Kingdom, Ali Aouad, Kamalini Ramdas, Alp Sungu

Designing subsidy programs presents a significant challenge: balancing policy efficiency with the flexibility of individual choice. “Paternalistic” approaches prioritize social outcomes, such as promoting the consumption of nutritious but less popular foods. This focus, however, can come at the expense of individual preferences, potentially leading to low uptake of the program by the intended beneficiaries. Conversely, policies that heavily weight individual choice may be inefficient. Empirical findings from a randomized controlled trial (RCT) on staple food subsidies in a low-income community illustrate this trade-off. In response, we propose an optimization model for subsidy design based on multinomial logit preferences, incorporating both in-kind subsidies and cash transfers. By leveraging technical insights from the revenue management literature, we identify the structure of optimal policies and develop practical solution methods. We calibrate our model using RCT data to generate counterfactual policies along the Pareto Frontier, aiming to balance efficient social outcomes with reduced paternalism.

New Methods for Inventory Policies

Contributed Session

Chair: Reuben Joseph, Binghamton University (SUNY)

1 - Advertising Selling Service and Selling Format in Online Retailing

JIANYUE WANG, The Hong Kong University of Science and Technology, Hong Kong, China, People's Republic of, Ki Ling Cheung, Albert Ha

We develop several game theoretic models to study the selling format and seller service strategies of an online retailer. We consider two common selling formats, agency selling and reselling, and one common seller services, advertising selling. When the online retailer offers advertising selling service, there is a cost sharing flexibility effect that creates more incentive for a seller to buy advertising under agency selling than under reselling. Moreover, a higher cost of advertising effort mitigates the double marginalization effect of wholesale price under reselling. We fully characterize the firms' equilibrium decisions. The online retailer prefers agency selling to reselling if the commission rate, demand signal accuracy or demand uncertainty is high, or the cost of advertising effort is low. Moreover, the online retailer prefers to sell advertising servcie if the commission rate, demand signal accuracy, demand uncertainty or cost of advertising effort is high. We show the impact of offering advertising selling on the profits of the seller and the supply chain. When more seller services are offered, the parameter space in which the equilibrium selling format is agency selling (respectively reselling) becomes larger (respectively smaller). Moreover, offering advertising service has a wider positive impact and a narrower negative impact when another seller service is available than when it is not available. The model is extended by considering the seller determines the selling format or including another seller service, information sharing service.

2 - Game-Theoretic Integration of Red Team Survey Data in Multi-Layer Security Systems

Ian Unson, University at Buffalo, Buffalo, NY, United States, Jun Zhuang

With the rise of domestic terrorism and soft target attacks, it is crucial we optimally allocate defensive resources across multiple security layers in venues such as airports, subway stations, sports venues and houses of worship. By allocating resources across these security layers properly we will aim to minimize the damages caused by a potential attacker or even be able to deter them. The attacker on the other hand, has the ability to observe how the defender allocates their resources and tries to circumvent the defenses we have laid out in order to maximize their objective. Building upon previous research in game theory, resource allocation problems and sociological surveys of participants playing the role of strategic attackers, we look at methods of updating the defenders' best response given updated attacker strategies. These attacker models have been built upon red teaming survey data collected from studies where participants played the role of an attacker. These attacker models not only take into account features within the game such as cost, payoffs, probability of success, etc. but also take into account characteristics of the attackers, such as numeracy skills and risk preferences. By utilizing these updated attacker models to solve for better Nash equilibria we aim to provide defenders with better decision-making tools that can deter or reduce the damages caused by soft target attacks.

3 - Dynamic Estimation of Random Effective Shelf Lives and Policy Optimization for Perishables

Ulku Gurler, Bilkent University, Ankara, Turkey

In multi-echelon supply chains, it is common that random demand and batch ordering processes result in effectively random shelf lives even when items have fixed lifetimes as issued by the uppermost echelon. Storage conditions at each location may further exacerbate this stochasticity rendering true remaining shelf lives unobservable. In this talk, I consider the dynamic estimation of effective shelf lives and optimization of simple, reasonable inventory control policies. Focusing on a single-location perishable inventory system in isolation as decoupled from the rest of the supply chain, an estimation procedure in the presence of censored shelf life observations and a heuristic policy optimization is provided. Effects of system parameters on estimation performance and relevant cost measures are discussed through numerical examples.

4 - Decision Support System with Integrated Ensemble Forecasting for Dynamic Inventory Control using System Dynamics

Reuben Joseph, Binghamton University (SUNY), Binghamton, NY, United States, Kunal Mangaonkar, Mohammad Khasawneh, Sreenath Chalil Madathil

Hospital inventory management ensures the continuous availability of medical supplies while aiming to reduce costs. Traditional methods, relying on heuristic rules and personal experience, often lead to overstocking, understocking, variable lead times, and inconsistent ordering processes that do not align with Group Purchasing Organization (GPO) and local contracts, resulting in higher prices.

This paper presents the Dynamic Inventory Optimization (DIO) model, a comprehensive solution to the challenges of hospital inventory management. The model tackles irregular inventory levels, inefficient ordering processes, high stock-outs, and low fill-rates. It incorporates a multi-type and multi-step time series forecasting and system dynamics framework known as the Dynamic Drum-Buffer-Rope (DDBR) replenishment approach. The model's effectiveness is further enhanced by using stacking ensemble learning models, including XGBRegressor, LSTM, Random Forest Regressor, and a Meta layer. These models outperform traditional algorithms in predicting future trends. The DIO model also introduces the innovative use of the Powell search Gradient descent algorithm, which dynamically adjusts inventory levels based on real-time data and usage trends. This approach prevents stock-outs, reduces inventory excess, and optimizes replenishment to reflect actual consumption patterns, significantly reducing costs and improving supply chain performance. Rigorous experimentation and simulation have validated the model's effectiveness, presenting a transformative tool for strategic stock allocation and decision support in hospital settings. Future work will focus on integrating the DIO model into real hospital ERP systems to generate real-time automated replenishment orders based on consumption trends with minimal manual interaction.

Keywords: hospital inventory optimization; system dynamics; Powell search algorithm; ensemble time-series forecasting

1 - Probabilistic Modeling for Uncertainty Quantification in Oil Pipeline Predictions

Bright Awuku, North Dakota State University, Fargo, ND, United States, Ying Huang, Nita Yodo, Eric Asa

Pipelines are critical infrastructure for transporting hydrocarbons, requiring massive capital investments. However, they are susceptible to failures that can lead to economic losses and environmental damage. Pipeline management agencies rely on predictions of failure events to plan maintenance, rehabilitation, and repair (MR&R) activities. State-of-the-art techniques yield point estimates without quantifying the uncertainty in failure-cause predictions, limiting their reliability for risk-based maintenance decisions. Reliable uncertainty quantification (UQ) of model predictions is essential for effective data-driven decision-making. While machine learning (ML) models do not inherently provide well-calibrated uncertainty estimates, more rigorous Bayesian techniques exist but are computationally expensive coupled with restrictive data assumptions. This paper proposes a conformal prediction methodology for assessing prediction uncertainty in ML-based oil pipeline failure causes, addressing the need for accessible and practical UQ techniques. The approach provides prediction regions with valid coverage probabilities, enabling quantification of uncertainties associated with failure-cause predictions to support risk-informed oil pipeline maintenance planning. The proposed methodology has implications for transportation infrastructure management by providing a framework to quantify uncertainties in condition predictions for assets like bridges, pavements, and railroads. The proposed method enhances confidence in using data-driven models for making informed MR&R decisions in critical transportation applications. This work contributes to an uncertainty estimation approach that overcomes the limitations of current techniques while being efficiently applicable to various ML model architectures without restrictive assumptions. The ability to generate valid prediction intervals enriches predictive analytics for more informed decision-making in asset management.

2 - Investigation of Condition Assessment Aiding Pavement Rehabilitation Decision-Making

Kathryn Quenette, North Dakota State University, Fargo, ND, United States, Xinyi Yang, Luyang Xu, Xingyu Wang, Ying Huang

The number of registered vehicles in the U.S. continues to rise, reaching approximately 282 million in 2021. This increase heightens concerns about detecting and repairing cracks before they become severe, since repairs can significantly extend the service life of the pavement at a low cost. To achieve this maintenance strategy, one solution is real-time monitoring, which tracks crack development to inform repairs. However, this method demands substantial manpower and traditional techniques typically only detect surface cracks, not those developing from the bottom up. To address these challenges, this study introduces a sensor system installed beneath the pavement, specifically using Fiber Bragg Grating (FBG) and distributed fiber optical sensors, embedded within the asphalt layers and between the asphalt and concrete

layers. This study aims to embed sensors beneath highway pavement to collect data for traffic analysis and pavement condition assessment, ultimately developing a new method for pavement integrity management planning. This proposed system would inform engineers when pavement replacement or crack sealing is necessary and allow users to monitor traffic and identify high-risk roads. Integrating sensors and creating this database would enable more efficient data access and informed pavement rehabilitation decisions.

3 - Empowering Super-stars or Rising-stars? Dynamics of the High-Speed Rail Network in China

Yucong Li, Tongji University, Shanghai, China, People's Republic of, Dongping Cao, Guangbin wang

The development of high-speed rail (HSR) systems as a critical component of the global 'infrastructure turn' is deeply embedded in complex regional socioeconomic contexts. Drawing on advances in actor-oriented network modelling and longitudinal inter-city HSR data in China during 2008-2022, this study explores how the evolution of the HSR network is dynamically and differentially underpinned by underlying attribute-based effects of regional socioeconomic scale and growth rate to balance the short-term efficiency and long-term equity of nationwide development. After controlling for related structure-based effects (e.g., transitive triads and balance) as well as attribute-based effects related to geographic, natural and cultural contexts, the results provide evidence that while the scale and the growth rate of regional economy and population both positively impact HSR tie formation, the impacts of attribute-based effects related to scale significantly diminish over time whereas the impacts of effects related to growth rate exhibit a significant strengthening trend. The results further illustrate that while the scale-related and growth-rate-related effects of regional economy function as distinct substitutes in driving the formation of HSR ties, the two corresponding effects of regional population significantly complement each other, providing clear evidence for the heterogeneous roles of regional economic and social contexts in underpinning HSR network dynamics. The findings provide implications for more effective and equitable regional socioeconomic development through strategic inter-regional HSR network planning.

4 - Rookie Routing and Other Simulated Submodel for Navigation Systems

Mingwei Guo, North Dakota State University, Fargo, ND, United States

This research aims to enhance road safety by providing alternative guidance tailored specifically for new and inexperienced drivers. By analyzing their driving behaviors, the study seeks to integrate adaptive navigation systems that offer real-time, context-sensitive assistance. The goal is to develop a guidance system that reduces stress and improves decision-making for rookie drivers, ultimately leading to safer and more confident driving experiences.

1 - Dynamically Learning Incentives for Load Control

Joshua Comden, NREL, Golden, CO, United States, Andrey Bernstein, Guido Cavraro

With the increase in variable renewable resources, and the electrification of many industries, it is becoming increasingly important to take advantage of flexible loads as controllable resources. However, incentivizing owners of flexible loads to relinquish some control in an effective and cost-efficient way has remained elusive. In this talk, we propose the use of a model-free feedback-based control algorithm that adjusts incentives for each flexible load owner based on the benefit to the system. One major advantage to adjusting incentives based on system benefit is that it rewards overall behavior instead of adjustments from a baseline which are difficult to accurately estimate in practice.

2 - A Contextual Bandit Approach for Value-Oriented Prediction Interval Forecasting

Yufan Zhang, University of California San Diego, San Diego, CA, United States, Honglin Wen, Qiuwei Wu

Prediction interval (PI) is an effective tool to quantify uncertainty and usually serves as an input to downstream robust optimization. Traditional approaches focus on improving the quality of PI in the view of statistical scores and assume the quality improvement will lead to a higher value in the power systems operation. However, such an assumption cannot always hold in practice. In this paper, we propose a value-oriented PI forecasting approach, which aims at reducing operational costs in downstream operations. For that, it is required to issue PIs with the guidance of operational costs in robust optimization, which is addressed within the contextual bandit framework here. Concretely, the agent is used to select the optimal quantile proportion, while the environment reveals the costs in operations as rewards to the agent. As such, the agent can learn the policy of quantile proportion selection for minimizing the operational cost. The numerical study regarding the day-ahead and real-time operation of a virtual power plant verifies the superiority of the proposed approach in terms of operational value. It is especially evident in the context of extensive penetration of wind power.

3 - From Sensing to Control: Strategies for Real-TIME Model Identification in Smart Grids

Vivek Khatana, University of Minnesota, Twin Cities (Minneapolis, MN, US), Minneapolis, MN, United States, Chin-Yao Chang

In this talk, I will focus on the problem of system model identification in power distribution networks through an innovative agent-based approach. The proposed method emphasizes distributed and localized model configurations to enhance robustness and address prevalent mislabeling issues within distribution grids. Departing from conventional practices of relying on historical data for offline model identification, the strategy presented in the talk introduce online model updates utilizing real-time data by employing only the latest measurements. This methodology offers significant advantages, including a large reduction in the communication network’s bandwidth requirements by minimizing the data exchanged at each iteration and enabling the model to adapt in real-time to disturbances. Furthermore, we extend the state-of-the-art from linear frameworks to more complex non-linear convex models. This extension is validated through numerical studies demonstrating improved voltage regulation performance. These advancements aim to fully exploit the capabilities of newly installed sensors in power distribution grids, significantly enhancing their practical value and utility.

4 - Dynamic Net Metering for Energy Communities

Ahmed Alahmed, Cornell University, Ithaca, NY, United States

We propose a grid-aware and social welfare maximizing market mechanism for an energy community that aggregates individual and community-shared energy resources under a general net energy metering (NEM) policy. Referred to as Dynamic NEM (D-NEM), the proposed mechanism dynamically charges/rewards community prosumers based on a two-part pricing rule that has a threshold-based structure. By formulating the decisions of the community manager and its prosumers as a Stackelberg game, we show that the proposed two-part pricing achieves a Nash equilibrium and maximizes the community's social welfare in a decentralized fashion while ensuring that prosumers' optimal decisions abide by the grid constraints. We prove that D-NEM is a stabilizing mechanism, as it achieves both individual and group rationalities. Finally, we argue that D-NEM is a just and fair mechanism to all community prosumers by showing that it conforms with the axioms of the cost-causation principle.

5 - Time series aggregation in energy system models with temporal and network constraints

Sonja Wogrin, Graz University of Technology, Graz, Austria, David Cardona-Vasquez

In this talk we discuss how to improve computational tractability of large-scale Linear Programs (applied to energy system model) that have network constraints and temporally-linked constraints, such as ramping constraints. We do this via a method - developed by us - that is referred to as basis-oriented aggregation. We present an extension of this method using machine learning, which allows for: decoupling of the large LPs, parallelization and in turn faster resolution times.

Optimizing Industrial and Construction Supply Chains

Contributed Session

Chair: Songi Kim, Inha University, 100 Inha-ro, Michuhol-gu, 22212

1 - Enhancing Safety Management in Circular Supply Chains through Blockchain Integration: A Stakeholder Perspective

Zhuowen Chen, Worcester Polytechnic Institute, Worcester, MA, United States, Joseph Sarkis, Yanji Duan, Abdullah YILDIZBASI

Safety management in circular supply chain (CSC) processes is critical yet insufficiently explored in operations management. The complexity of circular practices such as reuse, repurpose, remanufacture, and recycling raises challenges in maintaining safety standards. These challenges call for innovative management solutions to ensure effective safety protocols. Blockchain technology, recognized for its transparency and traceability, emerges as a promising tool for enhancing safety management across CSCs. The decentralized and immutable characteristics of blockchain make it particularly suitable for ensuring the integrity and reliability of safety data across the CSC. Stakeholder attitudes and perceptions play a pivotal role in the initial adoption of blockchain for CSC safety management. This study utilized a discrete choice experiment to explore the perceptions and willingness-to-pay among various stakeholders involved in CSCs. The methodology focuses on understanding stakeholder preferences concerning blockchain integration and their readiness to adopt blockchain-based safety management systems. The attributes examined focus on blockchain capabilities, safety and circularity practices within the supply chain. The findings of this study provide significant insights into the feasibility and desirability of blockchain applications for enhancing safety within CSCs. Moreover, the paper discusses the implications for future research and practice management of safety in CSCs. It suggests areas where further investigation is needed and highlights how managers can implement blockchain solutions in circular supply chains. These insights aim to contribute to the broader discourse on pursuing circular supply chains through innovation technologies.

2 - Operational Heterogeneity in U.S. Blast Furnaces

Elina Hoffmann, Carnegie Mellon University, Pittsburgh, PA, United States, Valerie Karplus, Chris Pistorius

Steel is vital to modern economies; however, its production is highly energy- and emissions- intensive. It is important to decouple steel production from CO_2 emissions for the sector to achieve its climate goals. While recent studies have focused on low-carbon steelmaking technologies, little attention has been paid to the CO_2 emissions reduction available with existing production processes. Operating existing technologies in a manner that minimizes CO_2 emissions can offer meaningful reductions in the near- and medium- term without the large capital outlays required of net-zero compatible routes. This study investigates the operational heterogeneity within- and across- a single steelmaking process technology, focusing on the blast furnace. Leveraging annual data on U.S. blast furnaces, we find considerable variation in operation resulting in direct emissions intensity estimates ranging from 1.32 to 1.67 tons of CO_2 per ton hot metal (tCO_2/tHM). The U.S. fleet may have been able to reduce cumulative CO_2 emissions more than 13% in the past eleven years had furnaces been operating at their most CO_2 efficient. We leverage additional datasets with high facility and temporal resolution to investigate how data aggregation may influence CO_2 emissions patterns, and in turn the impact of different decarbonization policies. Our work suggests that a global, 'best available technology', or even country-specific emissions factor fails to capture the heterogeneity in blast furnace operation. Policies incentivizing technologies to operate in a way that minimizes their CO_2 emissions may result in considerable emissions reductions that may not be realized when treating technology as a static monolith.

3 - Scheduling The Production of Prefabrication Construction Supply Chains Considering Variable Delivery Due Dates

Yong-Woo Kim, University of Washington, Seattle, WA, United States, Chung Ho, Zelda Zabinsky

In recent years, the construction industry has seen a significant increase in the application of prefabrication and modularization. Improving the efficiency on the operation and reliability on the delivery of prefabrication supply chains becomes critical for construction projects. However, the fluctuating nature of construction schedules poses challenges for the planning of prefabrication supply chains and adaptations when changes occur. The experience during the COVID-19 pandemic highlighted the impact of unavailable and delayed materials on construction projects, and the cancellation of construction projects on the supply chain. Our study focuses on prefabrication supply chains with multiple fabrication shops that consider the uncertainty of required delivery due dates to construction sites. An industry survey carried out by the authors reveals that changing the required delivery due dates of prefabricated products is common in construction projects. This presentation introduces a multi-objective stochastic programing model that facilitates the production planning of prefabrication products at multiple fabrication shops considering variable delivery times. The scenario-based solution balances minimal total cost with minimal total delay. Additionally, computational results are presented for an example problem with three fabrication shops, ten construction projects and fifteen products. The model allows fabricators to develop a robust set of optimal schedules that are capable of flexibly balancing cost and time reduction objectives.

4 - Optimizing a rolling process for manufacturing small steel bars using CART

Hyundeok Jang, Sungkyunkwan University, Suwon-si, Korea, Republic of, KwangHo Jeong, Dong-Hee Lee, Sung-Jun Lim, Sang-Hyeon Lee, Jong-Eun Lee

Small steel bars (SSBs) are common steel products manufactured through a rolling process. Surface defects on SSBs, which are critical quality problems of SSBs, are often incurred during the rolling process. In order to prevent the surface defects, key process variables affecting the surface defects should be identified and controlled. Recently, it has been common to collect a large amount of operational data from the rolling process which might include valuable information for improving the rolling process. This study attempts to obtain an optimal condition of rolling process variables where the surface defects are minimized by using a particular data mining strategy called classification and regression tree (CART). By analyzing node information from CART, which includes both leaf nodes and their ancestors, it is possible to identify several candidates for the optimal condition. These candidates are represented in hyperrectangle forms, demonstrating this approach's robustness and potential for substantial improvements in minimizing the surface defects.

5 - Service provider recommendation model for shared additive manufacturing supply chain: a case study

Songi Kim, Inha University, Incheon, Korea, Republic of, Kyung-A Kim, Hosang Jung

In the shared manufacturing platform, self-organized individuals can participate in manufacturing activities as service providers. When integrated with additive manufacturing (AM) technologies, shared manufacturing holds significant potential to produce large amounts of one-of-a-kind products. However, despite its potential, the concept still remains underexplored due to a scarcity of real-world examples. This study begins by analyzing the open-source assistive technology-sharing platform in South Korea, focusing on two main participant groups: people who need assistive technologies (such as older adults and people with disabilities) and people who contribute new designs of assistive technologies. It identifies the unmet needs of the two participant groups within this open-source platform. Building upon the analysis, we propose a shared AM supply chain that introduces a third participant type: manufacturers with AM machines who are willing to share their manufacturing capabilities and resources to produce assistive devices based on open-source designs. Subsequently, we develop the manufacturer recommendation model that provides the best AM manufacturer candidate to the customer, considering the manufacturing requirements of the assistive device, the customer's preferences between lead time and price, and the capabilities of the manufacturers. Finally, we apply the recommendation model to the case study with the example assistive device and potential manufacturers in Incheon, South Korea.

Bike Sharing and Urban Transportation

Contributed Session

Chair: Dimitrios Letsios, King's College London, London, United Kingdom

1 - Park Smart or Face the Music: Understanding Users' Orderly Parking Behavior of Dockless Shared Bikes from the Perspective of Deterrence Theory

Jianliang Hao, California State University, Chico, Chico, CA, United States, Zhenya Tang

The rapid growth of dockless bike-sharing has revolutionized urban transportation. However, the disorderly parking of dockless shared bikes has emerged as a critical challenge, significantly hindering the benefits of this system by causing obstructions, safety hazards, and public nuisance. This study aims to investigate users' orderly parking behavior of dockless shared bikes through the lens of deterrence theory. Our findings reveal that punishment severity, punishment certainty, personal norm, and descriptive norm have significant positive effects on users' attitudes towards orderly parking, which in turn positively influences their orderly parking behavior. This study contributes to the literature by extending the application of deterrence theory to the context of dockless bike-sharing and providing empirical evidence on the role of deterrence factors in shaping users' orderly parking behavior. Our findings offer valuable insights for bike-sharing operators and policymakers to develop effective strategies.

2 - The Paradox of Choice: Why Less is More for Crowdsourcing in Bike Sharing System

jinjia huang, Institute of Operations Research and Analytics, National University of Singapore, Singapore, Singapore, Zhenzhen Yan, Mabel C. Chou, Chung Piaw Teo

Inspired by New York's Citi Bike Bike Angels Program and Boston's Blue Bikes, we investigate the use of registered volunteers to reposition empty bikes for riders in a bike-sharing system. In Bike Angel programs or similar initiatives, volunteers move bikes from stations with excess bikes to stations in need of bikes in exchange for rewards. To reduce redundant re-balancing moves by volunteers, we propose a method that restricts the set of routes eligible for rewards. This demonstrates that limiting the deployment options for volunteers can actually make re-balancing activities more effective. Leveraging the modeling power of copositive cone programming, we develop a novel network design model tailored for re-balancing operations in crowdsourcing environments. Our model explicitly integrates critical factors such as volunteer availability, choice behaviors, and supply-demand variations, setting our work apart from traditional approaches in process flexibility and most existing studies. Our simulation experiments show that our approach provides a highly effective and cost-efficient solution to mitigate re-balancing issues in these systems.

3 - Vehicle Electrification and Grid Impact Assessment Tool for Informed Charging Infrastructure Expansion

Farhad Angizeh, Massachusetts Institute of Technology, Cambridge, MA, United States, Jessika E. Trancik

This paper reports on our three-layer electric vehicle (EV) charging infrastructure and grid impact assessment tool to aid policy stakeholders and developers in evaluating expansion strategies for widespread EV adoption. The first layer employs our *TripEnergy* model to estimate the energy needs for diverse personal vehicles, considering longitudinal travel patterns and driving behaviors. The second layer quantifies time-resolved energy needs to explore potential EV charging solutions (e.g., at home, workplace, public, and highway), guiding strategic charging infrastructure expansion. This layer also examines the role of behavioral modification in further enabling EV adoption. The third layer investigates the spatiotemporal grid impacts, informs project siting, and addresses whether upgrades are needed for distribution feeders and substation equipment to meet peak demands. Several case studies are demonstrated to highlight the key determinants of effective policy-making strategies and infrastructure expansion investments to support vehicle electrification.

4 - Static and Dynamic Inventory Rebalancing for Optimizing Service Loss in Bike Sharing

Dimitrios Letsios, King's College London, London, United Kingdom, Haoxiang Wang, Xinyi Ye

We elaborate on inventory rebalancing in bike sharing. The goal is to decide how to reposition bikes between the stations of a bike sharing network so as to optimize service loss. Previous work computationally demonstrates the benefits of dynamic compared to static rebalancing. We propose new optimal algorithms for both problem variants. On the negative side, we show that static rebalancing results in O(1/epsilon) proportion of successful requests. On the positive side, we prove that dynamic rebalancing achieves an Omega(1-epsilon) performance guarantee. To our knowledge, this is the first theoretical characterization of the dynamic rebalancing benefits compared to static rebalancing. Next, we consider the more general problem of optimizing service loss with bounded rebalancing costs. For both the static and dynamic variants, we develop new scalable mixed-integer approaches. We computationally substantiate the proposed approaches using data from the London bike sharing network.

5 - Repositioning in bike sharing systems with broken bikes considering on-site repairs

RUNQIU HU, The University of Hong Kong, Hong Kong, Hong Kong, WY Szeto

On-site repairs by repairmen can handle the broken bikes in a bike-sharing system and satisfy the usable bike demand simultaneously without vehicle repositioning for broken bike collection for off-site repairs. However, such option has not been jointly considered with vehicle-based repositioning for both usable and broken bikes in the literature.

This paper presents a mixed integer linear programming model for a static bike repositioning problem with broken bikes combining vehicle-based bike delivery/collection and labor-based on-site repairs. The model aims to minimize the total cost of user dissatisfaction and the carbon emissions generated during the repositioning. Two model variants are also developed for scenario comparison. An algorithm combining the hybrid genetic algorithm with a greedy heuristic was proposed to solve the problem. Results show introducing an on-site repairman can lead to lower user dissatisfaction but more carbon emissions in some cases. Moreover, the introduction of a repairman proves effective in reducing the total cost of user dissatisfaction and carbon emissions when the broken bike inventories at deficit stations are approximately half of the usable bike shortages. With an on-site repairman, the lowest total cost and carbon emissions occur when the broken bike quantity is exactly the usable bike shortage. After the number of broken bikes exceeds that shortage, rebounds in the total cost and carbon emissions are observed. Furthermore, separating the routes of the repairman from the truck can reduce the total cost of user dissatisfaction and carbon emissions, with decreased user dissatisfaction but occasionally slightly higher carbon emissions.

FICO/Amazon

Invited Session

Technology Showcase

1 - From Data to Decisions with the Help of Gen AI and Great Optimization Technology

Dinakar Gade, FICO, Bozeman, MT, United States, Oliver Bastert

You have a team with a great analytics background. They have created advanced analytical tools using Python, R, or your current optimization solver. They managed to derive insights from your data and figured out what the best path forward is. But the tools remain cumbersome to use and are not accessible by business domain experts and business users. It is time to put these critical analytical insights into the hands of the business – with the help LLMs and great optimization technology.

In this tutorial, you'll learn how FICO's Xpress Optimization capabilities make it possible to embed your analytic and optimization models within business user-friendly applications. See how to supercharge your models with simulation, fast and robust optimization, reporting, what-if analysis, and agile extensibility for your ever-changing business. We will demonstrate how LLMs can help developing models and configure the solution as well as efficiently guide the business user.

2 - Data-Driven Supply Chain Optimization: Demand Forecasting and Deep Reinforcement Learning

Sohrab Andaz, Amazon, New York, NY, United States

Inventory control is a complex real-world problem that involves handling challenges like seasonal demand, time-varying costs, complex inventory arrival dynamics, and various real-world constraints. In modern supply chain management, effective inventory control requires more than traditional optimization methods. Over the past few years, the Amazon SCOT Demand Forecasting and RL groups have pioneered deep learning models that distill Amazon-scale data into deployable time-series forecasting models and control policies designed to handle these complexities.

In this talk, we will explore both approaches, demonstrating:

1. How deep learning techniques naturally handle supply chain forecasting challenges, including seasonality, cold starts, diverse product categories, and forecast volatility.
2. How deep reinforcement learning can move inventory control beyond the predict-then-optimize framework, allowing practitioners to directly optimize business objectives using historical data.

This talk will also draw on real-world deployment experiences of both deep learning and deep RL policies.

Summit - 346

Market Dynamics and Financial Modeling

Contributed Session

Chair: Qiang Gao, Baruch College, City University of New York, New York, NY, United States

1 - Augmented Bayesian Estimation for Portfolio Analysis

Yan Wang, The University of Hong Kong, Hong Kong, China, People's Republic of, Peng-Chu Chen

This paper introduces a Bayesian framework for estimating expected asset returns for portfolio selection. This framework relies on a perturbed linear model that predicts out-of-sample portfolio returns, where expected returns are the coefficients to be estimated. The model is fitted to a synthetic dataset via Bayesian regression, and the estimator is computed using a Gibbs sampler, which is both consistent and asymptotically efficient. In a simplified setup, the gap between the out-of-sample mean return of a mean-variance portfolio constructed using this estimator and the best possible out-of-sample mean return is bounded above by the prediction error of the perturbed linear model. As the size of the synthetic dataset increases, the prediction error decreases, narrowing the return gap. This finite sample property ensures that portfolios constructed using our estimator outperform the classical mean-variance, global minimum-variance, and naive portfolios out-of-sample, yielding higher out-of-sample average returns and Sharpe ratios, with or without norm constraints on portfolio weights, as demonstrated by empirical studies.

2 - GameStop in the Lab: Short Squeezes in Experimental Asset Markets

Bradley Paye, Virginia Tech, Blacksburg, VA, United States, Alec Smith, Ross Spoon

This study establishes the existence of explosive short squeezes in laboratory asset markets. The task design includes naturalistic margin and short-sale constraints such that traders can take short and leveraged positions. In most markets, we observe price bubbles in early rounds and the emergence of a small set of traders who take relatively large short positions. Several markets produce outcomes consistent with a short squeeze, featuring explosive price increases that are associated with closing short positions. Following squeezes, prices fall but remain upwardly dislocated from fundamentals for a prolonged period. We also examine how market structure and trader heterogeneity generate squeezes. High cash-to-asset ratios increase the likelihood of large upward price dislocations associated with short squeezes. Our results demonstrate that short-sale constraints can exacerbate, rather than mitigate, asset price bubbles.

3 - Deep hedging of equity linked securities

Jae Wook Song, Hanyang University, Seoul, Korea, Republic of, Namhyoung Kim, Dongwon Ryu

Deep hedging, a sophisticated framework leveraging deep learning for derivative hedging, exhibits commendable efficacy in managing vanilla options. This framework requires the generation of simulated price series for the underlying assets. Equity-linked securities (ELS), as structured financial instruments, derive their returns from the price movements of one or more underlying equities. Consequently, deep hedging applied to ELS requires a time series generation model that captures the correlation among the underlying assets. This study introduces a deep hedging framework designed to effectively manage the risk associated with ELS products featuring intricate pay-off structures. First, a deep learning-based financial time series generation model is employed to generate price series that reflect the asset correlations. Then, a hedger is trained using deep learning to minimize losses for each position, aligned with the specific payoff structure of the ELS. The findings of this study confirm that the proposed approach reduces hedging expenses for ELS compared to the conventional Black-Scholes-Merton framework.

4 - All That Glitters Is Not Gold: The Impact of Certification Costs In Online Labor Markets

Qiang Gao, Baruch College, City University of New York, New York, NY, United States, Jiaru Bai, Paulo Goes, Mingfeng Lin

Third-party skill certification is widely used to address the ubiquitous information asymmetry between workers and employers. A natural way to encourage workers to take certification exams is to make the certification tests free. However, neither theoretical nor empirical studies have examined how employers respond to the decision to offer free tests. This research fills this gap. First, we develop a stylized model to hypothesize the possible effects of zero-cost certification tests on employers' recruitment decisions and their transaction amounts (i.e., contract prices) with workers. Second, we empirically test these hypotheses by exploiting a natural experiment when one of the largest online labor markets unexpectedly removed its certification test fees. Contrary to the platform’s expectations, the offering of free certification tests *reduced* the signaling value of the certifications: Employers’ preference for certified workers decreased (both in terms of hiring likelihood and price paid); more importantly, such preference change appeared economically justified, as workers certified under the new policy are *less* likely to deliver high-quality work. Furthermore, the fall in signaling value is particularly high for inexperienced workers who are still in the process of accruing reviews and are thus more dependent on certifications to secure work. The findings remained consistent over the longer term during our study period. Finally, this study finds evidence that employers have made irrational decisions in hiring after implementing zero-cost certification tests. Our results strongly support the study’s theoretical propositions and have important implications for platforms and practitioners in online labor markets.

Sourcing Innovation

Invited Session

Technology, Innovation Management and Entrepreneurship

Chair: Ersin Korpeoglu, University College London, London, United Kingdom

Co-Chair: Ramazan Kizilyildirim, UCL, LONDON, E14 3SP, United Kingdom

1 - Changing Course: How Analogies Direct Pivots

Jeremy Hutchison-Krupat, University of Cambridge, Cambridge, United Kingdom, Panos Markou

Innovation is exciting because it is full of immense possibility. However, immense possibility is difficult to comprehend. To resolve this, an innovator must interpret or frame the opportunity to reduce the many possible dimensions to just a few prioritized dimensions, which translates to a strategy and a course of action. Yet, rarely does an innovative endeavor follow its original course of action or result in an outcome that replicates what was originally envisioned. Indeed, successful innovation evolves through iterative experimentation to implement a strategy. However, the strategy itself may also require adaptation, otherwise known as a pivot. An effective pivot requires the abandonment of a current strategy, and a decision on a new, more effective, course of action. We conduct two experiments to study how experience with analogous settings enables innovators to address these challenges and pivot effectively. These experiments require individuals to make sense of a difficult problem, adopt and iteratively implement a strategy, and experience progress towards an objective. Then, new information is revealed, which renders the initial strategy ineffective, and requires individuals to pivot their strategy to achieve success. Our results show that analogies are a remarkably effective means to enable individuals to pivot. Moreover, we disentangle the properties of analogies and provide insights on which types of analogies are most likely to prompt a pivot. Our results reveal that while analogies can increase the likelihood to pivot, some types of analogies may lead an innovator to change course, but do so for the wrong reason.

2 - Optimal Feedback in Asymmetric Contests

Hossein Nikpayam, ESMT Berlin, Berlin, Germany

Contests, in which contestants compete at their own expense for prizes offered by a contest holder, have become the foundational primitive of many theories of competition. Recently, the focus in contest research has turned to the role of in-contest performance feedback. The extant literature on feedback has focused on specific ad-hoc policies in symmetric contests and hence failed to more broadly characterize optimal feedback policies. In this paper we solve a general formulation of an asymmetric contest involving feedback, and thus characterize the optimal feedback policy in a very wide class of (stochastic) feedback policies. We find that, in many settings where informative feedback is useful, feedback is optimal when it is both truthful and fully informative.

3 - The Value of Private Feedback in Trial-and-Error Innovation Contests

Zhenyu Hu, National University of Singapore, Singapore, Singapore, Zhi Chen, Yufei Zhu

Firms have increasingly turned to innovation contests as a means of procuring complex industrial innovations from their supplier base. At the start of the contest, the buyer announces the innovation challenge and the award in the form of a valuable supply contract. To address the challenge, it is common that suppliers adopt the trial-and-error approach to develop solutions, and then submit them to the buyer for evaluation as the contest progresses. In some contests, the buyer privately reveals the interim performance of developed solutions to the suppliers during the trial-and-error process (private feedback), but in others, the buyer withholds such information (no feedback). Motivated by such divergent practices, we seek to understand whether providing private feedback (or not) results in higher profits for the buyer. We find that providing private feedback is more profitable for the buyer when either there are many evaluation rounds or when the cost of a trial is high. We further uncover two sources of the value of private feedback: it incentivizes suppliers to conduct more trials ("quantity effect") in a more efficient way ("quality effect"). In contrast, no feedback results in higher profits for the buyer when there are few evaluation rounds and when the cost of a trial is low.

4 - Exclusive OR Not? An Experimental Analysis of Parallel Innovation Contests

RAMAZAN KIZILYILDIRIM, UCL, LONDON, United Kingdom, Cigdem Gizem Korpeoglu, Ersin Korpeoglu, Mirko Kremer

We study parallel innovation contests where organizers seek innovative solutions to a set of problems from independent solvers with limited (financial, time, cognitive) resources. We analyze whether (and when) organizers should discourage solvers from participating in more than one contest. We test contest theory based on a game-theoretic model using controlled laboratory experiments. In the model, a solver's likelihood of winning a contest is determined by the quality of her solution, which improves with her effort and is also influenced by some output uncertainty. Prior theoretical work suggests that organizers should discourage solvers from participating in parallel contests in environments with low output uncertainty, where contest outcomes are primarily driven by solver efforts. In this case, organizers benefit from solvers focusing all of their efforts on a single "exclusive" contest rather than splitting their efforts across multiple "non-exclusive" contests. Our experimental findings depart from theoretical predictions in terms of both solvers' effort choices and the relative profitability of different contest formats. Our main result (and key managerial insight) is that non-exclusive contests are attractive to organizers even in environments with low output uncertainty where theory advocates exclusive contests. We link this result to behavioral tendencies that affect both the average and variability of solvers' efforts in ways that favor non-exclusive contests over exclusive ones.

Advanced Modeling and Optimization in Transportation and Manufacturing

Contributed Session

Chair: Xianyue Peng, University of Calfornia, Davis, 4848 El Cemonte Avenue, Davis, CA, United States

1 - Development of artificial neural network-based finite element method surrogate models for predicting material deformation in H-shaped steel intermediate rolling process

Seokkyu Pyo, Sungkyunkwan University, Suwon-si, Korea, Republic of, Hyundeok Jang, Dong-Hee Lee, Sangjin Lee, Hyunseok Jung, Jong-Eun Lee

Structural mechanics simulation for process design in the steel industry relies primarily on a finite element method. The finite element method is traditional and accurate, but the higher the desired resolution, the more time and computational resources are required. The computational resource issue is even more significant in the rolling process, which involves continuous rolling mills. This study proposes an artificial neural network (ANN)-based surrogate model to predict the deformation of H-shaped steel in the intermediate rolling process as an alternative to the finite element method. The finite element simulation data was collected by a fractional factorial design, and features reflecting the relationship between geometry and deformation were added to increase the explanatory power. The trained ANN model successfully predicts the deformation of steel under the untrained process condition, showing a performance of R2 = 0.993 while reducing the prediction time from 6 hours to 5 seconds.

2 - A Strategic Decision-Making Tool for Last Mile Delivery Considering Autonomous Vehicles

Raghavan Srinivasan, BSU, Muncie, IN, United States, Joseph Szmerekovsky

An aggregate delivery capacity plan for last mile delivery services is explored using simulation. This simulation is done considering the use of permanent resources, seasonal resources, crowdsourcing capacity and use of autonomous vehicles or robots to meet the demand. The objective here is to achieve the lowest operational cost in the event of resource attrition and missed deliveries. The results from the simulation show that autonomous vehicles can reduce dependence on seasonal capacity. This use of automation can both decrease cost and increase service level. Also, the operational challenges associated with the use of automation for last mile delivery aggregate capacity planning are discussed.

3 - Application of Agent-Based Simulation Model in Demand Estimation of CNG Stations

Yinglei Li, Breakthrough - a USVenture company, BELLEVUE, WA, United States, Andy Martinelli

An energy company attempts to leverage the information of shipment volume and routes to better estimate the current and potential demand their station locations could possibly generate. To achieve this goal, an agent-based simulation model has been developed to quantify the potential fuel demand of each CNG station based on the flow of network loads. In the simulation model, each agent represents a driver. Each agent can be customized by the users to specify the driver’s habits and preference in terms of eating, parking for resting, bathroom, and brand requirement during the tours. Different probability functions can be assigned to the agent to determine when and where an agent would stop and re-fuel. The results can help the energy company with the following: generating different agent scenarios, evaluating consumption estimates at each CNG station, partnering with transportation providers and shippers who utilize the stations, and planning for new complimentary locations.

4 - Optimal Lock Maintenance of the U.S. Inland Waterway Transportation System under Uncertainty Using Deep Reinforcement Learning

Maryam Aghamohammadghasem, University of Arkansas, Fayetteville, AR, United States, Jose Azucena, Haitao Liao, Shengfan Zhang

The interconnected infrastructure, including the lock and dam systems, is essential to the inland waterway transportation system (IWTS) 's continued operation. However, as the IWTS ages, more unforeseen events, such as failure, occur, which results in major unplanned maintenance, transportation delays, and financial losses.

A Python-enhanced NetLogo simulation tool is developed to assess the effects of lock-induced disruptions on IWTS. Deep reinforcement learning is used to determine the best maintenance plans that maximize cargo throughput on the IWTS. The locks are grouped together using a machine-learning technique, and individual repair teams are assigned to each cluster. If the corresponding repair teams for every individual cluster are overworked, outsourcing to other idle groups with higher expenses may be an option. Additionally, a maintenance group consists of a variety of individuals with varying specialties who are assigned to a particular failure requiring specialized knowledge. The repair crew's travel time is factored in to make it seem more realistic.
The potential of the developed simulation and machine learning-based approach for IWTS maintenance optimization is demonstrated through a case study of the lower Mississippi River system and the McClellan-Kerr Arkansas River Navigation System.

5 - A multi-scale perimeter control and route guidance system for large-scale road networks

Xianyue Peng, University of California-Davis, Davis, CA, United States, Hao Wang, Shenyang Chen, Michael Zhang

Perimeter control and route guidance are effective ways to reduce traffic congestion and improve traffic efficiency by controlling the spatial and temporal traffic distribution on the network. This study presents a multi-scale perimeter control and route guidance framework for controlling traffic in large-scale networks. The network is first partitioned into several subnetworks (regions) with traffic in each region governed by its macroscopic fundamental diagram (MFD), which forms the macroscale network (upper level). Each subnetwork, comprised of actual road links and signalized intersections, forms the microscale network (lower level). At the upper level, a joint perimeter control and route guidance model solves the region-based inflow rate and hyper-path flows to control the accumulation of each region and thus maximize the throughput of each region. At the lower level, a perimeter control strategy integrated with a backpressure policy determines the optimal signal phases of the intersections at the regional boundary. At the same time, a route choice model for vehicles is constructed to meet hyper-path flows and ensure the intra-region homogeneity of traffic density. The case study results demonstrate that the proposed joint control outperforms either perimeter control or backpressure control in regulating regional accumulation, thereby achieving higher throughput.

Sequential Decision Making

Invited Session

OPT: Integer and Discrete Optimization

Chair: Rohan Ghuge, Georgia Institute of Technology, Atlanta, United States

Co-Chair: Yihua Xu, Georgia Institute of Technology, Atlanta, GA, United States

1 - Exponential Pricing Algorithms for Online Resource Allocation

Rohan Ghuge, Georgia Institute of Technology, Atlanta, GA, United States, Yifan Wang, Sahil Singla

Online resource allocation problem is a central problem in many areas of Computer Science, Operations Research, Economics, and Networks. In this problem, requests arrive sequentially, and each request can be satisfied in multiple ways, each consuming a certain amount of resources while generating different values. The objective is to maximize the overall value without exceeding the {budget} for any resource. Of particular interest in this problem is the design of \emph{pricing} algorithms that present each incoming request with prices for the resources, enabling the request to make a value-maximizing decision based on current resource prices. The goal is to achieve a $(1+\epsilon)$-approximation to the hindsight optimum, where $\epsilon>0$ is a small constant.

2 - Stochastic Scheduling: Strategies for Abandonment Management

Yihua Xu, Rice University, Houston, TX, United States, Rohan Ghuge, Sebastian Perez-Salazar

We explore a job scheduling model driven by applications with impatience, such as in call centers and cloud computing. We have a single server and n jobs with known non-negative values. These jobs also have unknown stochastic service and departure times with known independent distributional information. We aim to design a policy that maximizes the expected total value obtained from jobs run on the server. Natural dynamic programming formulations face the curse of dimensionality. Furthermore, our problem is demonstrably NP-hard. Hence, we focus on policies that can provide good approximation factors compared to the optimal value. We provide a compact linear program relaxation that upper bounds the performance of the optimal policy and examine the quality of this LP relaxation by bounding its integrality gap by constants. As a byproduct of our analysis and mild assumptions on the service times supports, we provide a polynomial-time computable policy that is a (1/2)(1 − 1/e) approximation of the optimal expected reward. Our methodology is flexible, allowing additional constraints to be incorporated. We develop efficient approximation algorithms with provable guarantees for extensions like job release times, deadlines, and knapsack constraints. Additionally, we consider jobs having independent and identically distributed service times and show that the natural greedy policy guarantees half of the optimal expected value. We provide empirical validation of our policies via numerical experiments.

3 - New guarantees for online selection over time

Sebastian Perez Salazar, Rice University, Houston, TX, United States

We revisit the prophet inequality over time problem. In this problem, the decision-maker can choose how long to select a value instead of stopping with only one realized value, as in the classical setting. We provide improved bounds based on density arguments and convex optimization.

4 - Scheduling Flexible Jobs with Predicted Lengths Non-preemptively for Minimum Span

Mozhengfu Liu, Northwestern University, Evanston, IL, United States, Xueyan Tang

We study an online model in which a sequence of so-called flexible jobs, each with a starting deadline and a processing length, are released over time. The jobs are to be started by an online scheduler no later than their starting deadlines and will run non-preemptively. Non-preemption means that once the job is scheduled to start, it is not allowed to be paused and resumed later. There is no limit on the number of simultaneously running jobs. The objective is to minimize the span, i.e., the time duration for which at least one job is running. We investigate the problem in the learning-augmented setting: when each job is released, a predicted length rather than the real length of it is revealed. We show asymptotically tight deterministic bounds for its competitiveness. Minimizing the span (sometimes called active time) is foundational to solving busy time problem. The busy time problem, in which flexible jobs are to be scheduled into machines to minimize the accumulated running time of all machines, is closely related to optimizing the monetary costs of renting machines in cloud computing and saving the power usage of machines in energy-efficient computing.

Advances in Optimization for Machine Learning

Invited Session

OPT: Nonlinear Optimization

Chair: Pratik Rathore, 94305

Co-Chair: Zachary Frangella, Stanford University, Stanford, CA, United States

Co-Chair: Madeleine Udell, Stanford University, Stanford, CA, 94305, United States

1 - Convex Optimization Reformulations for Deep Neural Networks

Mert Pilanci, Stanford University, Stanford, CA, United States

In this talk, we introduce an analysis of deep neural networks through convex optimization. We begin by introducing exact convex optimization formulations for ReLU neural networks. This approach demonstrates that deep networks can be globally trained through convex programs, offering a globally optimal solution. Our results further establish an equivalent characterization of neural networks as high-dimensional convex Lasso models. These models employ a discrete set of wedge product features, and apply sparsity-inducing convex regularization to fit data. This framework provides an intuitive geometric interpretation where the optimal neurons represent signed volumes of parallelotopes formed by data vectors. We introduce numerical optimization schemes to obtain near-optimal solutions efficiently.

2 - Online Learning Guided Quasi-Newton Methods: Improved Global Non-Asymptotic Guarantees

Ruichen Jiang, University of Texas at Austin, Austin, TX, United States, Qiujiang Jin, Aryan Mokhtari

Quasi-Newton (QN) methods are popular iterative algorithms known for their superior practical performance compared to Gradient Descent (GD)-type methods. However, the existing theoretical results for this class of algorithms do not sufficiently justify their advantage over GD-type methods. In this talk, we discuss our recent efforts to address this issue. Specifically, in the strongly convex setting, we propose the first “globally” convergent QN method that achieves an explicit “non-asymptotic superlinear” rate. We show that the rate presented for our method is provably faster than GD after at most $O(d)$ iterations, where d is the problem dimension. Additionally, in the convex setting, we present an accelerated variant of our proposed method that provably outperforms the accelerated gradient method and converges at a rate of $O(\min\{1/k^2, \sqrt{d \log k }/ k^{2.5}\})$, where k is the number of iterations. To attain these results, we diverge from conventional approaches and construct our QN methods based on the Hybrid Proximal Extragradient (HPE) framework and its accelerated variants. Furthermore, a pivotal algorithmic concept underpinning our methodologies is an online learning framework for updating the Hessian approximation matrices. Specifically, we relate our method's convergence rate to the regret of a specific online convex optimization problem in the matrix space and choose the sequence of Hessian approximation matrices to minimize its overall regret.

3 - Schedule-Free Learning

Aaron Defazio, Meta Platforms, Inc., New York, NY, United States

Existing learning rate schedules that do not require specification of the optimization stopping time T are greatly out-performed by learning rate schedules that depend on T. We propose an approach that avoids the need for this stopping time, exhibiting state-of-the-art performance compared to standard schedules across a wide range of problems, including both convex problems and large-scale deep learning problems. Our method introduces no additional hyper-parameters over standard SGD with momentum. Our method is a direct consequence of a new theory we develop that unifies scheduling and iterate averaging. An open source implementation of our method is available.

4 - Policy Optimization with Compatible Mirror Approximation

Lin Xiao, FAIR @ Meta, Seattle, WA, United States, Zhihan Xiong, Maryam Fazel

We propose Compatible Mirror Policy Optimization (CoMPO), a framework that incorporates general function approximation into policy mirror descent methods for reinforcement learning. In contrast to the popular approach of using the squared L2 norm to measure function approximation errors, CoMPO uses the Bregman divergence induced by the same mirror map as in policy projection. Such a compatibility bridges the gap between theory and practice: not only does it lead to fast linear convergence with general function approximation, but it also includes several well-known practical reinforcement learning methods as special cases, including Soft Actor-Critic, immediately providing them with strong convergence guarantees.

5 - A Non-stochastic Control Approach to Optimization

Xinyi Chen, Princeton University, Princeton, NJ, United States, Elad Hazan

Selecting the best hyperparameters for a particular optimization instance, such as the learning rate and momentum, is an important but nonconvex problem. As a result, iterative optimization methods such as hypergradient descent lack global optimality guarantees in general.We propose an online nonstochastic control methodology for mathematical optimization. First, we formalize the setting of meta-optimization, an online learning formulation of learning the best optimization algorithm from a class of methods. The meta-optimization problem over gradient-based methods can be framed as a feedback control problem over the choice of hyperparameters, including the learning rate, momentum, and the preconditioner. We show how recent methods from online nonstochastic control can be applied to develop a convex relaxation, and obtain regret guarantees vs. the best offline solution. This guarantees that in meta-optimization, given a sequence of optimization problems, we can learn a method with performance comparable to that of the best method in hindsight from a class of methods. We end with experiments on a variety of tasks, from regression to deep neural network training, that demonstrate the practical effectiveness of our method.

Summit - 422

Recent Advances of Interior Point Methods for (Non)linear Optimization

Invited Session

OPT: Nonlinear Optimization

Chair: Madeleine Udell, Stanford University, Stanford, CA, 94305, United States

Co-Chair: Wenzhi Gao, Stanford University, Stanford, CA, 94305, United States

1 - When Does Primal Interior Point Method Beat Primal-Dual?

Wenzhi Gao, Stanford University, Stanford, CA, United States, Huikang Liu, Madeleine Udell, Yinyu Ye

It is widely accepted that primal-dual interior point method (IPM) is the most efficient IPM variant for linear optimization. In this paper, we show this is not always the case by inspecting IPM in the pure primal form. We show that stability of the primal scaling matrix enables several computational techniques for acceleration, including efficient preconditioning with iterative methods, approximate search direction generation and robustness to perturbation.

2 - Clarabel: An Interior Point Solver for Conic Optimization

Yuwen Chen, University of Oxford, Oxford, United Kingdom, Paul Goulart

The homogeneous self-dual embedding (HSDE) is a popular technique that unifies optimality and infeasibility detection of a convex problem and has been widely used in convex interior-point solver. However, it only allows a linear cost in the objective and we need to eliminate the quadratic term in the objective function, replacing it with an epigraphical upper bound and an additional second-order cone constraint in the objective.

We presented the interior-point solver, Clarabel, for conic optimization with quadratic objectives by using the homogeneous embedding for infeasibility detection, which tackled the issue of transforming QPs into SOCPs. The solver is fully written in both Julia and Rust languages. We support second-order cones, exponential cones, power cones and positive semidefinite cones in Clarabel. Our solver is competitive with the cutting-edge conic solvers on various benchmarks and outperforms them in terms of time and numerical stability on QPs and SOCPs.

3 - The Nonsymmetric Conic Optimizer in Copt

Joachim Dahl, Cardinal Operations, Copenhagen, Denmark

Over the last two decades there has been much research into interior-point algorithms for conic optimization, especially linear programming, second-order cone and semidefinite optimization, which has been implemented in several commercial and research packages.

In comparison, extensions to other (non-symmetric) cones are much less studies. In this talk we consider one such extension, namely the exponential cone, which has recently been added to the COPT conic optimizer.

4 - Polynomial-TIME Interior-Point Methods for Convex Optimization Beyond Symmetric Cones

Mehdi Karimi, Illinois State University, Normal, IL, United States, Levent Tuncel

Since Nesterov and Nemirovski’s seminal book in 1994, polynomial-time interior-point (IP) methods for convex optimization have been extensively investigated. While the focus for creating solvers has been on optimization over symmetric cones, several recent efforts have aimed to develop robust solvers for optimization over other interesting convex sets, such as the exponential cone and the quantum relative entropy (QRE) cone. This presentation introduces our Domain-Driven IP algorithms and the corresponding solver DDS. Our approach and the solver DDS accept every convex set represented by a computationally efficient self-concordant barrier. We present the recent developments in our approach and software DDS. In addition to accepting problems with several function/set constraints, the newest version, DDS 2.2, has modifications for solving QRE programming problems, potentially combined with many other constraints. Concluding the presentation, we showcase numerical results demonstrating the efficacy of DDS in solving diverse problem classes.

5 - Recent Advances in Quantum Interior Point Methods

Tamás Terlaky, Lehigh University, Bethlehem, PA, PA, United States, Mohammadhossein Mohammadisiahroudi, Zeguan Wu, Pouya Sampourmahani

Various Quantum Interior Point Methods (QIPMs) were proposed and analyzed in the past years for Conic Linear Optimization (CLO) problems. Those include: Inexact Infeasible, Inexact Feasible QIPMs and Quantum Central Path algorithms. Some QIPMs are enhanced with preconditioning and iterative refinement methodologies. Novel quantum variants inspired novel classic variants too.

In this talk, at a high level, we review the key features of the various QIPMs and their classic counterparts, and highlight the advantages and challenges offered by quantum computing, the pros and cons of the algorithm paradigms.

Summit - 423

Reformulations and Solution Approaches for Mixed-Integer Nonlinear Optimization

Invited Session

OPT: Global Optimization

Chair: Andres Gomez, University of Southern California, Los Angeles, CA, United States

1 - Real-TIME Solution of Mixed-Integer Quadratic Programs Using Decision Diagrams

Shaoning Han, National University of Singapore, Singapore, Singapore, Andres Gomez, Leonardo Lozano

We consider mixed-integer quadratic optimization problems with banded matrices and indicator variables. These problems arise pervasively in statistical inference problems with time-series data, where the banded matrix captures the temporal relationship of the underlying process. In particular, the problem studied arises in monitoring problems, where the decision-maker wants to detect changes or anomalies. We propose to solve these problems using decision diagrams. In particular we show how to exploit the temporal dependencies to construct diagrams with size polynomial in the number of decision variables. We also describe how to construct the convex hull of the set under study from the decision diagrams, and how to deploy the method online to solve the problems in milliseconds via a shortest path algorithm.

2 - Isotonic Optimization with Markup Costs

Shuai Li, Georgia Institute of Technology, Atlanta, GA, United States, Xin Chen, Weijun Xie

This paper addresses a new mixed-integer nonlinear optimization problem that extends the generalized isotonic optimization problem by incorporating markup cost whenever a change occurs. This formulation considers a directed path graph and puts isotonic constraints on each arc. The costs incurred at each node consist of a markup cost and a convex cost, and our objective is to minimize the overall costs. The formulation covers various applications, such as reduced isotonic regression, stochastic lot-sizing, joint inventory control, and pricing with costly price markdown. After proving an optimality condition, we introduce a shortest path algorithm achieving $O(n^2 \log n)$ complexity to solve this problem to optimality. Besides, after assuming the minima of those convex functions follow a non-decreasing order, we can improve computational efficiency to $O(n)$. We then extend this model by making the graph from a directed path to an arborescence and show that the current shortest path algorithm fails generally.

3 - New Finite Hierarchy for Disjoint Bilinear Programs

Mohit Tawarmalani, Purdue University, West Lafayette, IN, United States

We introduce new hierarchy for disjoint bilinear programs. These hierarchies utilize rational functions as product-factors and improve upon relaxations obtained using disjunctive programming and reformulation-linearization technique providing new insights relating these hierarchies with one another. Our hierarchies have geometric and algebraic underpinnings and converge at a finite level. Finally, we leverage our techniques to develop convex relaxations for concave-convex functions and new hierarchies for facial disjunctive programs.

4 - A Convexification-Based Outer-Approximation Method for Convex and Nonconvex MINLP

Zedong Peng, Purdue University, West Lafayette, IN, United States, Kaiyu Cao, Kevin Furman, Can Li, Ignacio Grossmann, David Bernal Neira

The advancement of domain reduction techniques has significantly enhanced the performance of solvers in mathematical programming. This work delves into the impact of integrating convexification and domain reduction techniques within the Outer- Approximation method. We propose a refined convexification-based Outer-Approximation method alongside a Branch-and-Bound method for both convex and nonconvex Mixed-Integer Nonlinear Programming problems. These methods have been developed and incorporated into the open-source Mixed-Integer Nonlinear Decomposition Toolbox for Pyomo-MindtPy. Comprehensive benchmark tests were conducted, validating the effectiveness and reliability of our proposed algorithms. These tests highlight the improvements achieved by incorporating convexification and domain reduction techniques into the Outer-Approximation and Branch-and-Bound methods.

5 - A Polyhedral Study on L-Natural-Convex Minimization and Its Mixed-Integer Extension

Qimeng Yu, Université de Montréal, Montréal, QC, Canada, Simge Kucukyavuz

L-natural-convex functions are a class of nonlinear functions defined over integral domains. Such functions are not necessarily convex, but they display a discrete analogue of convexity. In this work, we explore the polyhedral structure of the epigraph of any L-natural-convex function and provide a class of valid inequalities. We show that these inequalities are sufficient to describe the epigraph convex hull completely, and we give an exact separation algorithm. We further examine a mixed-integer extension of this class of minimization problems and propose strong valid inequalities. We establish the connection between our results and the valid inequalities for some structured mixed-integer sets in the literature.

Summit - 424

Stochastic Programming with Endogenous Uncertainty.

Invited Session

OPT: Optimization Under Uncertainty

Chair: Samuel Affar, University of Tennessee, Knoxville, Knoxville, TN, United States

1 - A Successive Refinement for Solving Stochastic Programs with Decision-Dependent Random Capacities

Samuel Affar, University of Tennessee, Knoxville, Knoxville, TN, United States, Hugh Medal

We study a class of two-stage stochastic programs in which the second stage includes a set of components with uncertain capacity, and the expression for the distribution function of the uncertain capacity includes first-stage variables. Thus, this class of problems has the characteristics of a stochastic program with decision-dependent uncertainty. A natural way to formulate this class of problems is to enumerate the scenarios and express the probability of each scenario as a product of the first-stage decision variables; unfortunately, this formulation results in an intractable model with a large number of variable products with high-degree. After identifying structural results related to upper and lower. bounds and how to improve these bounds, we present a successive refinement algorithm that successively and dynamically tightens these bounds. Implementing the algorithm within a branch-and-cut method, we report the results of computational experiments that indicate that the successive refinement algorithm significantly outperforms a benchmark approach. Specifically, results show that the algorithm finds an optimal solution before the refined state space becomes too large.

2 - Searching Model with Decision-Dependent Uncertainty

Luis Novoa, James Madison University, Harrisonburg, VA, United States

We propose a decision-dependent uncertainty stochastic programming model, along with reformulations and tailored decomposition solution methods, aimed at prescribing optimal search and patrolling strategies to locate a target that follows an uncertain path across discrete time periods. We assume that the target's path selection is contingent on proposed surveillance strategies—number and positioning of mobile searchers and static sentries with diverse capabilities— consequently making uncertainty modeling decision-dependent. This dependency is addressed through the definition of a coupling function that describes how the probability distribution associated with the random target's path is influenced by surveillance decisions. The problem at hand results in a large-scale nonconvex MIP, which can be reformulated as a MILP requiring tailored solution approaches. We propose an efficient branch-and-Benders-cut single-tree solution algorithm that leverages the unique structure of our problem.

3 - Informative Path Planning with Limited Adaptivity

Rayen Tan, University of Michigan, Ann Arbor, MI, United States, Rohan Ghuge, Viswanath Nagarajan

We consider the informative path planning (IPP) problem in which a robot interacts with an uncertain environment and gathers information by visiting locations. The goal is to minimize its expected travel cost to cover a given submodular function. Adaptive solutions, where the robot incorporates all available information to select the next location to visit, achieve the best objective. However, such a solution is resource-intensive as it entails recomputing after every visited location. A more practical approach is to design solutions with a small number of adaptive "rounds", where the robot recomputes only once at the start of each round. In this paper, we design an algorithm for IPP parameterized by the number k of adaptive rounds, and prove a smooth trade-off between k and the solution quality (relative to fully adaptive solutions). We validate our theoretical results by experiments on a real road network, where we observe that a few rounds of adaptivity suffice to obtain solutions of cost almost as good as fully-adaptive ones.

4 - Probing-enhanced stochastic programming

Jim Luedtke, University of Wisconsin-Madison, Madison, WI, United States, Jeff Linderoth, Zhichao Ma

We consider a two-stage stochastic program where the decision-maker has the opportunity to obtain information about the distribution of the random variables X through a set of discrete actions that we refer to as probing. Probing allows the decision-maker to observe components of a random vector Y that is jointly-distributed with X. We propose a three-stage optimization model for this problem, where the first-stage variables select components of Y to observe. In the case that X and Y have finite support, a model of Goel and Grossmann can be applied to obtain a formulation of this problem whose size is proportional to the square of cardinality of the sample space of the random variables. We propose to solve the model using bounds obtained from an information-based relaxation, combined with a branching scheme that enforces the consistency of decisions with observed information. The branch-and-bound approach can naturally be combined with sampling in order to estimate both lower and upper bounds on the optimal solution value even for problems with continuous distribution. We demonstrate the approach on instances of a stochastic facility location problem.

Summit - 425

Advancements in Urban Transit Systems

Contributed Session

Chair: Bolong Zhou, The Hong Kong University of Science and Technology, Hong Kong, N/A, Hong Kong

1 - Optimizing the schedule of UAV-assisted urban subway inspection services

Bolong ZHOU, The Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Wei Liu, Hai Yang

The periodic inspection and maintenance of subway facilities are essential for ensuring passenger safety. However, the current manual inspection practices conducted by expert engineers are time-consuming, costly, and pose risks to workers. Unmanned aerial vehicles (UAVs) offer a promising solution for automatically inspecting subway facilities. This paper investigates an operational-level synchronized optimization problem, aiming to determine an optimal inspection timetable while simultaneously optimizing working schedules for both human teams and UAVs. Demand heterogeneity is taken into account since the variety of facilities and equipment in subway tunnels may have different required inspection cycles. A compact Mixed-Integer Linear Program (MILP) model is developed to solve this NP-hard problem. We propose an enumeration-based reformulation and develop an exact algorithm that combines Benders decomposition and Dantzig-Wolfe decomposition within a branch-and-price framework to solve the MILP model efficiently. The approach is strengthened by implementing several acceleration strategies. Extensive numerical experiments have been carried out. The results show that our proposed optimization model and algorithms can find the optimal solution for real-world scale instances, resulting in cost savings and improved efficiency. Furthermore, we highlight the benefits of integrated optimization by comparing our solution approach with a sequential method that addresses inspection timetables and working schedules separately.

2 - Mobility, Equity, and Economic Impact of Transit in the Chicago Metropolitan Region

Omer Verbas, Argonne National Laboratory, Lemont, IL, United States, Taner Cokyasar, Joshua Auld, Aymeric Rousseau, Seamus Joyce-Johnson, Jim Aloisi, Anson Stewart, Gabriel Barrett

Transit has a low modal share in most US metropolitan regions due to high car ownership and sparse, suburban land use outside the urban core. However, it is still the backbone of urban travel. In the Chicago Metropolitan Region, the regional modal share of transit was 5. 5% before the pandemic, and it is expected to be around 3.1% in 2025 due to increased negative perception of transit and shift in telecommuting patterns. This study focuses on a complete transit removal scenario in Chicago metropolitan region resulting in a removal of ~25K scheduled service trips and 1.35M single-leg riders. The scenario also envisions a 30% increase in car ownership, where households without cars buy a car, and households with a single car buy an additional one. Using POLARIS, an agent-based travel demand modeling and multimodal traffic simulation platform, both scenarios – 2025 baseline and transit removal – are simulated. Compared to baseline, average speeds decrease by 16% in the region and 33% in the city. Similarly, average travel times increase by 14% in the region and 35% in the city. In the entire region, 12% (1.6M) of non-work activities and 9% (1.9M) of overall activities get cancelled. In the city, 27% (1.0M) non-work activities, and 20% (1.2M) of overall activities get cancelled. The activity cancellations are suffered disproportionately by women and low-income groups.

3 - Evaluation of Travel Demand Models for On-demand Multimodal Transit Systems

Ryan Rodriguez, Georgia Institute of Technology, Atlanta, GA, United States, Hongzhao Guan, Pascal Van Hentenryck

Travel demand modeling is important for the design of transit systems because it allows planners to identify and analyze the markets and produces ridership estimates. This presentation introduces a travel demand modeling study for a specific type of transit systems: On-Demand Multimodal Transit Systems (ODMTS). ODMTS are an emerging transit concept that seamlessly integrates high-frequency fixed-routes like rail and bus rapid transit with on-demand shuttles into a single synchronized system, addressing the first/last mile problem faced by transit agencies. In recent years, ODMTS have been deployed in two cities in Georgia: Atlanta (2022) and Savannah (2024). With information collected from these real-world deployments, this study combines data from multiple sources such as demographic, geographic, and historical trip data to generate estimations at the census block level. Machine learning frameworks are employed to classify the demand of each census block into the following categories: empty, low, medium, or high. A detailed analysis between intra-dataset evaluation and inter-dataset evaluation has provided valuable insights into understanding the travel behavior of ODMTS riders. Specifically, intra-dataset evaluation studies the travel behavior within specific urban areas, serving as a basis for developing a complicated mode choice model---a critical piece overlooked in a few previous ODMTS studies. Moreover, through inter-dataset evaluation, this study reveals the machine learning framework's potential effectiveness in transferring demand knowledge across different urban areas, which is crucial for informing the design and development of future ODMTS programs.

4 - Designing Incentive Bundles for Multimodal Transportation Systems

Jason Lu, University of Michigan, Ann Arbor, MI, United States, Neda Masoud

In Mobility-as-a-Service (MaaS) systems, the incorporation of multimodal transport, such as transit and ridesharing, has the potential to provide greater accessibility, operational efficiency, and user convenience of mobility services. To encourage effective system utilization and improve social equity in a multimodal setting, incentives such as subsidizing costs for users could be developed. In this paper, we propose a novel incentive scheme that bundles subsidies across multiple modes for a MaaS system under a fixed budget. Bundles are designed to encourage multimodal usage of the system with the goal of enhancing overall social welfare across all system users and improving equity within the system. An optimization framework is developed to find an optimal incentive strategy that subsidizes user costs across combinations of multiple modes. Numerical results on a multimodal network demonstrate that incentive bundles can significantly improve social welfare and system efficiency compared to traditional MaaS Systems while also bridging the equity gap among users.

5 - PICASA - Optimal Capacity allocation in Supply chain for better speed offering

V N Sai Anjani Kumar Kudupudi, Flipkart India Private Limited, Bengaluru, India, Aditya Siva Sai Prasanth Bandaru, Gowtham Bellala, Vikas Goel, Anjan Goswami, Rishabh Bhat, Sarvesh Desai

Delivery Speed is one of the critical metrics for an e-commerce company. Fulfillment centers (FC) of an e-tailer typically assign approved orders to waves (defined by some cut-off timings) and dispatch the shipments to the next destination in the supply chain. During periods of high demand (e.g., a sale event), orders end up getting assigned to future waves leading to spillage in the supply chain impacting the delivery speed. Our goal is to design a system that will ensure a consistent delivery speed and experience to key buying cohorts. A buying cohort corresponds to a combination of customer segment (e.g., customers enrolled in loyalty programs) and product segment (e.g, speed sensitive products). Spillage protection to key buying cohorts is achieved by reserving dedicated capacity at various assets/nodes in the supply chain. However, a capacity segmentation strategy can lead to inefficient utilization of these capacities. As a result, it becomes imperative that we optimize for trade-offs between spillage protection and capacity under-utilization to provide better speed. This problem is especially challenging during sale events when the demand patterns are highly unpredictable. In this work, we developed a stochastic optimization model which dynamically determines the optimal allocation of capacity across the cohorts with an objective of providing better protection to key buying cohorts under minimal under-utilization. This model has been deployed in major sales and helped us to offer 1600 bps differential 2-day delivery speed for the high priority cohort.

Middle Mile Optimization and Service Network Design

Invited Session

Transportation Science and Logistics (TSL)

Chair: Sarah Powell, University of Iowa, Iowa City, IA, United States

1 - Underground Freight Transportation for Middle Mile Delivery

Sarah Powell, University of Iowa, Iowa City, IA, United States, Ann Campbell, Mojtaba Hosseini

The use of tunnels for package delivery is receiving increased attention as it provides an efficient and environmentally friendly alternative to truck delivery. Tunnel delivery removes trucks from the road decreasing traffic, emissions, and noise pollution, and provides a more reliable method of delivery in cases of extreme weather. We consider the use of tunnels for middle mile delivery and evaluate the impact on the number of orders that can arrive at neighborhood distribution centers in time for next-day delivery, which is a priority in e-commerce. We provide an integer programming model for this new problem and consider different options for combining and sorting deliveries. We determine the tunnel capacity needed to meet all next-day delivery requirements. We provide insights on optimal dispatch schedules for tunnel vehicles when tunnel capacity is binding. In a set of computational tests, we compare the use of tunnels to truck delivery in the middle mile and determine the conditions under which using tunnels allows higher levels of next-day delivery.

2 - Valid Inequalities for Service Network Design Models

Lacy Greening, Arizona State University, Tempe, AZ, United States, Santanu Dey, Alan Erera

This presentation will discuss two new classes of valid inequalities for service network design models (applicable to both arc- and path-based formulations). Results from a computational study using both industry-based and the so-called CANAD instances will demonstrate their effectiveness to strengthen the linear programming (LP) relaxations.

3 - Dynamic Service Network Design

Alexander Bode, TU Braunschweig, Braunschweig, Germany, Mike Hewitt, Dirk Mattfeld, Marlin Ulmer

Companies in the LTL industry have a network of transshipment locations and transportation services between them. Generally, transportation services are scheduled tactically to deliver the commodities being shipped. However, it is possible that the demand for transportation services exceeds the supply. Commodities that cannot be delivered with the regular transportation services are called excess cargo. Our problem deals with the issue of how companies can transport excess cargo as cost-efficiently as possible with the help of third-party providers. Excess cargo cannot be predicted and occurs randomly. Decisions must therefore be made dynamically in order to be able to react to the new commodities that arise. We therefore do not consider the entire time horizon but use a rolling horizon approach to decompose the problem over time and solve it in individual steps. The problem is modeled using a MIP and a sequential decision process. Intermediate destination nodes are introduced as a concept. The solution method is based on this concept and a two-part Cost Function Approximation (CFA) is developed, which can estimate the costs of decisions as accurately as possible. The first part of the CFA estimates the near future by estimating the consolidation possibilities of the known commodities. The second part of the CFA estimates the costs in the distant future and uses a measure based on slack to evaluate the progress of the commodities. We test our CFA on real data and the results clearly show the effectiveness of the method.

4 - Improvement Heuristics for Large Scale Ltl-Service Network Design

Ravit Pichayavet, Georgia Tech ISyE, Atlanta, GA, United States, Daniel Ulch, Alejandro Toriello, Alan Erera

This work presents heuristic solution approaches that solve an extra large-scale less-than-truckload service network design problem. The problem comes primarily from the strategic flow and load planning of our industry partner, one of the biggest parcel delivery companies in the US. The problem seeks to jointly decide the flow and load planning, where the flow plan specifies the sequence of sorting facilities (location) for package flow, and the load plan determines a detailed timing for a truck dispatch (load) that carries packages to their destinations. We introduce a marginal cost path algorithm, a local search improvement heuristic that iteratively selects a local neighborhood and re-paths flow commodity when marginal cost saving exists. We benchmark the algorithm with slope-scaling heuristics, a well-known heuristic approach that can be applied up to the size of our instance. Two computational experiments motivated by the practical use cases of our industry partner, including primary-flow plan improvement that seeks to find adjustments to the company's existing plan and contingency response plan that seeks to find cost-efficient adjustments in response to the capacity disruption at the sorting facility, are conducted.

Summit - 428

Crowdsourced Logistics Operations

Invited Session

TSL: Freight Transportation

Chair: Ali Sabzevari Zadeh, University of Alabama, Tuscaloosa, AL, United States

1 - Crowdshipping Problem with Dynamic Compensations and Transshipment

Barış Yıldız, Koç University, Istanbul, Turkey, Ali Sardag, Kerim U. Kizil

Rapid urban growth and consequent increase in e-commerce demand make urban logistics a harder task than ever. The growing size of urban delivery operations not only entails operational challenges but also generates several negative externalities, such as increased traffic, pollution, noise, and accidents. This trend creates a pressing need for efficient delivery mechanisms that are more economical and environmentally friendly than existing systems. Crowdshipping, wherein ordinary members of the society partake in delivery operations for a small compensation, is one of the answers that cater to this need and has attracted considerable research interest recently. However, designing compensation mechanisms to prompt efficient participation from the public remains largely unexplored in the literature. In this study, we devise a dynamic compensation scheme for crowdshipping operations in a many-to-many express delivery framework, where the crowdshipper compensations are determined based on spatial and temporal distributions of the delivery demand and continually updated during the service time to leverage the crowd participation as needed. To address the resulting complex network management problem, we derive analytical solutions for compensation optimization and use these results along with effective pruning strategies to build a lookup table to simultaneously determine package routes and compensation offers in real time. Computational studies and extensive simulations conducted with real-world data show that our proposed approach can provide significant cost savings and considerably reduce operational costs and other transport-related negative externalities when compared to classical delivery modes, crowdshipping with static compensations, and crowdshipping without transshipment.

2 - Query-based Request Reallocation for Collaborative Urban Transportation

Steffen Elting, University of Vienna, Vienna, Austria, Jan Fabian Ehmke, Margaretha Gansterer

To reduce costs and greenhouse gas emissions in the last-mile delivery sector, multiple transportation service providers can engage in an auction-based horizontal collaboration. With the help of a central auctioneer, delivery orders are reallocated among the carriers so that the total driving duration can be decreased compared to isolated planning. To minimize information sharing, the auctioneer conducts a combinatorial auction which usually requires an exponential number of bids to be communicated where each bid is equivalent to solving a complex vehicle routing problem. We investigate an integrated, query-driven approach to limit the number of bids while still obtaining an efficient order allocation. Rather than executing the bundling and bidding steps of the auction separately, the auctioneer iteratively poses a few value queries to the carriers at a time and uses their responses to train regression models that are used as surrogate fitness functions when searching for the next queries. We simulate a collaboration in the city of Vienna, Austria, with three carriers and 50 customers each. Our results show that the proposed approach can be up to 10% better than the sequential benchmark from the literature and up to 20% better than a random benchmark. However, these results depend on the number of value queries that the auctioneer is allowed to ask, as the regression-based approaches require sufficient training data to work well.

3 - Would you deliver your neighbor's package? Crowdsourced last-mile delivery

Ali Sabzevari Zadeh, University of Alabama, Tuscaloosa, AL, United States, Iman Dayarian

We study the problem of last-mile delivery in the context of an e-retailer offering two types of services: same-day delivery through parcel lockers (PL), and next-day home delivery (HD). Daily, PL customers place their orders to pick up from their preferred parcel locker and period, among the list of available ones. HD orders placed the day before, must be delivered by the end of the day. To reduce the workload of corporate drivers for the delivery process of HD orders, PL customers may be employed. At the time of order placement, PL customers are presented with a list of pre-generated HD order bundles, where they can bid on a subset. If a PL customer's bid wins, the associated bundles of HD orders are delivered to the parcel locker for the winning PL customer to collect along with their orders, which they then deliver to the respective HD customers in return for store credits. This problem is stochastic due to the dynamic nature of PL order arrivals. Hence, in each period, the retailer decides which bids to accept, which HD orders to dispatch, and which ones to postpone, aiming at minimizing the total operational costs. Further, routes are planned for vehicles, in each period, to deliver selected HD orders to customers and PL orders, along with those in the accepted HD bundles, to designated PLs before customer-chosen periods. To predict future PL orders and crowd-shipping capacity, we develop a stochastic look-ahead approach.

4 - Towards Equitable Workload Distribution in Last-Mile Delivery for the Gig Economy: The Dispatch Zone-Wave Problem

Abhay Sobhanan, University of South Florida, Tampa, FL, United States, Hadi Charkhgard, Iman Dayarian

Last-mile delivery (LMD) remains consistently crucial, constituting a significant expense within the logistics framework. In response to the escalating demand for faster delivery services, many retailers are turning to independent crowd couriers for order fulfillment. Crowdsourced drivers differ in terms of the time they become available, the capacity of their vehicles, and their next destinations, among other factors. Therefore, while crowdshipping revolutionizes LMD, its distinguishing factors introduce new operational challenges. One significant challenge is ensuring uninterrupted operations in crowdshipping, which is influenced by drivers' satisfaction in participating frequently in delivery tasks. Satisfied drivers are more likely to undertake subsequent jobs, maintaining operational flow. To ensure driver satisfaction, an equitable workload assignment is crucial since it directly impacts the compensation paid to and the cost incurred by each driver. In this talk, we propose a practical equity-aware framework tailored to LMD in crowdshipping environments. Using the proposed framework, several key research questions will be explored.

5 - Touting occasional drivers for mid-haul delivery

Margaretha Gansterer, University of Klagenfurt, Klagenfurt, Austria, Simona Mancini, Chefi Triki

Outlet villages offer online purchasing services combined with home delivery. Aiming at efficient last mile delivery, in our study we propose to exploit in-store customers to perform mid-haul deliveries on their way back home. The drawback of the system is that the presence of in-store customers willing to serve a specific area is strongly affected by uncertainty. In order to decrease the negative effect of this uncertainty, we propose to adopt a touting strategy to incentivize potential in-store customers to come to the outlet on a specific day and to perform, if needed, a mid-haul delivery, by offering them a discount voucher. In addition, the company may exploit customers who express their interest to act as occasional drivers, directly on site. Such customers may make bids to cover one or more areas. After receiving all the bids, the company decides through an auction system which ones to accept. The problem is formulated as a two-stage stochastic problem. We apply the model to instances based on a real-world case involving an outlet village located in the North-West of Italy. The obtained results show the benefit of applying the proposed mixed distribution system rather than making use of the owned fleet only.

Nonlinear Learning and Optimization

Contributed Session

Chair: Yijin Ni, Georgia Institute of Technology, 10 Perimeter Summit Blvd NE, Brookhaven, GA, 30319, United States

1 - A Uniform Concentration Inequality for Mmd: Robustness to Functional Transformations

Yijin Ni, Georgia Institute of Technology, Brookhaven, GA, United States, Xiaoming Huo

Embedded in the *reproducing kernel Hilbert space* (RKHS), *maximum mean discrepancy* (MMD) is a metric for probability measures. Being successfully applied in a wide range of problems, the optimized MMD-based estimators through the choice of the kernel are proven to be consistent.

In this paper, we construct a uniform concentration inequality for the unbiased *U*-statistic estimate of the squared MMD, showing the uniform consistency of MMD from another perspective. More specifically, given a functional class *G* equipped with finite Gaussian complexity, we show that for any functional transformation g in class *G*, considering the transformed pair of probability metrics, the difference between the *U*-statistic estimate and the expected squared MMD has a probability bound that is irrelevant with the specific function *g*. In optimization problems that involve MMD in their objectives, through the choice of functional transformation applied to the involved random variables, the uniform convergence bound confirms the consistency of the MMD-based estimators in minimization, maximization, and minimax problems. Considering different choices of the functional class *G*, the application scenarios of the uniform concentration inequality include: (i) the bandwidth tuning phase of MMD in two-sample tests; (ii) the construction of a generative model through MMD in the case of model contamination; (iii) the choice of a Grassmannian in dimension reduction problems based on MMD; (iv) the independent component analysis problem based on MMD; (v) the machine learning models of MMD, such as generative adversarial networks, variational auto-encoders.

2 - Concurrent stochastic optimization and derivative estimation of quantiles for chance constrained problems

Felisa Vazquez-Abad, Hunter College-CUNY, Manhattan, NY, United States

Optimization under probability (or chance) constraints is known to be a challenging problem. Generalizing our preliminary results for one-dimensional problems, we study here the general model where the constraints may depend on a stochastic process parametrized by the control variable of the optimization problem. The distribution of the underlying process is not known and only samples of it are available, so the optimization algorithm must be built for streaming data. Instead of formulating the constraints as probability contraints, we use the alternative form in terms of quantile constraints, which is known to yield more efficient gradient-based algorithms. Common methods for solving such problems make use of advanced statistical functional estimation of the distribution function directly, using approximations that are provably convergent. Such approximations provide explicit functions of the control parameter that can be then used to build consistent estimators of derivatives of the quantile with respect to the control parameter. One of our main contributions is to propose a dynamic estimator of the derivative of the quantile directly (without using approximations of the distribution) that can be implemented as the optimization updates take place. Because quantiles are commonly estimated using the complete history of samples obtained, the computational challenges include an undesirable super-linear running time. We show that older samples can be re-used when updating the control parameters in the stochastic approximation algorithm, rather than having to re-start the estimation. We explicitly take account of the algorithmic complexity of the numerical methods for solving the stochastic optimization problem.

3 - Learning Regions of Interest for Bayesian Optimization with Unknown Constraints

Fengxue Zhang, University of Chicago, Chicago, IL, United States, Yuxin Chen

Optimizing objectives under constraints, where both the objectives and constraints are black box functions, is a common scenario in real-world applications such as the design of medical therapies, industrial process optimization, and hyperparameter optimization. One popular approach to handle these complex scenarios is Bayesian Optimization (BO). However, when it comes to the theoretical understanding of constrained Bayesian optimization (CBO), the existing framework often relies on heuristics, approximations, or relaxation of objectives and, therefore, lacks the same level of theoretical guarantees as in canonical BO. In this paper, we rely on the insight that optimizing the objective and learning the constraints can both help identify the high-confidence ***regions of interest*** (ROI) that potentially contain the global optimum. We propose an efficient CBO framework that intersects the ROIs identified from each aspect to determine the general ROI. Then, on the ROI, we optimize the acquisition functions, balancing the learning of the constraints and the optimization of the objective. We showcase the efficiency and robustness of our proposed CBO framework through the high probability regret bounds for the algorithm and extensive empirical evidence.

4 - Wasserstein-based kernels for unsupervised learning

Alfredo Oneto, ETH Zurich, Zurich, Switzerland, Blazhe Gjorgiev, Giovanni Sansavini

In numerous data clustering applications, the representation of objects often extends beyond vectorial data, posing a challenge. The bag-of-vectors representation has emerged as a versatile approach for encapsulating complex objects across various research domains. Additionally, leveraging tools based in computational optimal transport theory, particularly the Wasserstein distance, offers a robust geometric framework for treating these objects as probability distributions. This study explores the utilization of kernel methods harnessing the Wasserstein distance to craft a clustering framework tailored to such objects. Initially, we present a method for efficiently approximating Wasserstein distances via linear optimal transport. Subsequently, a kernel based on the Wasserstein distance is developed, ensuring its positive definiteness. Moreover, we integrate two clustering validity indices, which facilitate the comparison of clustering results obtained using kernels with varying parameters. To evaluate our framework, experiments are conducted on extensive datasets comprising power distribution graphs, employing kernels defined over both bags-of-vectors and vectorial data. The findings validate the efficacy of our proposed framework in adeptly handling complex objects within a clustering context.

Drone Routing

Contributed Session

Aviation Applications

Chair: Ang Li, The Hong Kong Polytechnic University

1 - Mothership-based drone routing optimization via branch-and-price-and-cut

Reza Mirjalili, University of Houston, Houston, TX, United States, Gino Lim, Taewoo Lee

This paper presents a mothership-based drone routing problem to deliver parcels or visit waypoints for surveillance. Mothership (e.g., vehicle) follows a given sequence of fixed locations while operating drones onboard. Drones are allowed to serve multiple locations (i.e., customers) on a single flight. Small drones offer speed and cost advantages over ground vehicles. However, they face operational constraints such as limited payload and battery duration. Therefore, this paper aims to optimize the schedule of the mothership and drone flight paths by minimizing the total drone flight duration and waiting times of drones and the vehicle. Because solving the optimization model is computationally challenging, we propose a branch-and-price-and-cut (BPC) method, utilizing column generation to generate feasible flights and assignments. We introduce two valid inequalities to strengthen the lower bound of BPC: one employing dual optimal values for a stronger lower bound on flight numbers, and another mitigating the Big-M constraint effect for accurate waiting time calculation. Unlike existing BPC pruning policies based on LP relaxation, we propose a stronger bound based on a branching strategy, resulting in the reduction of the BPC tree size. Results demonstrate ~1.9-5% average gap improvement per node with the proposed bound and ~0.01-0.2% average gap improvement with the proposed cuts for 10-40 customer instances.

2 - Optimizing Vaccine Access: Equity-Focused Drone Delivery in Disease-Prone Region

Hamid Sayarshad, Cornell University, Ithaca, NY, United States

This research presents a novel framework that combines dynamic disease modeling and an optimization approach to enhance the fairness and equity of vaccine distribution through drone-based delivery. The objective is to ensure equal access to vaccines across different regions, including rural areas and small cities. Our approach seeks to achieve an optimal allocation of vaccines by considering regional infection rates and vaccination coverage, enabling effective prediction of vaccine demand. To accomplish this, we utilize a region-specific, dynamic disease model that factors in population size, infection rates, and vaccination rates. By integrating this dynamic disease model with a well-designed delivery network, we minimize travel and healthcare costs resulting from insufficient vaccination coverage, while also ensuring fair distribution. Our model takes into account logistical considerations specific to drone vaccine delivery, such as payload capacity, flight range, and regional vaccine demand. These considerations are crucial in addressing the unique challenges faced by rural areas and small cities in accessing healthcare services. To validate our model, we conducted a study on drone-based vaccine delivery during the COVID-19 pandemic, focusing specifically on Orange County and small cities. The findings of this study have significant practical implications for the development and implementation of drone-based vaccine delivery systems that prioritize fairness and equitable access to vaccines, particularly in smaller cities and rural areas.

3 - Drone-truck Arc Routing Problems

Sung Hoon Chung, Binghamton University, Binghamton, NY, United States, Emad Alenany

We address a Drone-Truck Arc Routing Problem (DT-ARP) for which an integer programming model is developed based on the modeling concept called an operation. The considered problem involves adding a new drone feature to the rural postman problem. A heuristic approach is proposed, where local search and simulated annealing methods are used to select initial truck tours. We also address the best combination of drone launch and recovery nodes to minimize the makespan. Numerical examples are presented to discuss the effectiveness of the proposed model and heuristic for DT-ARP.

4 - A Two-Echelon Bidirectional Energy Supply Problem with Uncrewed Electric Aerial and Ground Vehicles

Hyunhwa Kim, University of Illinois Urbana-Champaign, Urbana, IL, United States, Eleftheria Kontou

In emergency response settings or contested environments, energy supply to various demand nodes is constrained due to damaged or insufficient power infrastructure. Electric uncrewed ground (UGVs) and aerial vehicles (UAVs) can play a notable role in providing backup power, discharging energy directly to meet demand and recharging en-route if necessary. This research aims to design a two-echelon multimodal logistics system for bidirectional energy supply. The first echelon is distributing deployed UGVs and UAVs from a depot to satellite locations. In the second echelon, these vehicles travel from satellites to meet energy demand with discharging their batteries and recharge en-route if needed. We formulate this system as a bidirectional electric vehicle location-routing problem, which we solve using column generation to optimize vehicle routes and determine satellite locations to minimize energy consumption of the system. We conduct numerical experiments on transportation networks and perform sensitivity analysis, assessing the impact of the battery capacities of UGVs and UAVs on the optimal energy supply.

5 - Congestion Sensitive Strategies for Drone-based Multimodal Last-mile Urban Parcel Delivery

Ang Li, The Hong Kong Polytechnic University, Kowloon, Hong Kong

Urban parcel delivery has emerged as a high growth market, and the resulting delivery traffic can pose great challenges in dense urban areas. There is growing interest in supplanting the conventional model of a dedicated delivery person operating a van to alternatives featuring new classes of vehicles such as drones, autonomous ground vehicles, cargo bikes and non-motorized vehicles. This work proposes combined delivery strategies using trucks, cargo bikes and drones. We develop and compare multi-modal delivery strategies with various scenarios in both single and multiple echelon last-mile delivery network. We plan the delivery route, schedule, mode selection, facility location, task assignment in the developed optimization models. Then, a congestion model is developed and integrated to the multimodal delivery model through Macroscopic Fundamental Diagram (MFD) and traffic simulations. The congestion model relates multimodal delivery strategies and congestion effects on road network. We evaluate the benefit of multi-modal delivery in both uncongested and congested transportation networks. Results show that delivery models with multiple vehicles modes in both single- and multi- echelon networks are more efficient in terms of total delivery cost than traditional truck only scenario. The multi- modal delivery strategies in two- echelon networks outperform other strategies in extremely congested situations. We suggest taking advantage of synergistic operation among emerging vehicle types, especially drones for more efficient parcel delivery.

Optimizing Service Networks and Systems

Contributed Session

Chair: arvind rathore, 14068

1 - An iterative commodity aggregation and disaggregation method for service network design problems

Louis Bonnet, LAAS-CNRS, Université de Toulouse, Toulouse INP, Toulouse, France, Simon Belieres, Mike Hewitt, Sandra Ulrich Ngueveu

Service Network Design Problems (SNDP) have been widely studied in the OR literature but become rapidly intractable as the number of commodities increases. We aim to alleviate the impact that the number of commodities may have on the problem difficulty through the use of aggregation and disaggregation techniques. In this context, we define a relaxation of the original problem that is based on the idea of aggregating commodities, reducing the number of flow variables and, thus, the size of the problem. However, this reduction in size may lead to solutions that are not feasible to the original problem. To circumvent this issue, we propose an invalidity detection procedure that identifies the underlying reasons for this infeasibility. We also introduce a disaggregation scheme that intends to tighten the solution space of the aggregated model by refining the information available. To control the size of the aggregated model, our scheme aims to solely disaggregate information on a subset of arcs for which it appears necessary. Ultimately, starting from the initial relaxation, we propose an iterative solution approach that (i) solves the aggregated SNDP, (ii) checks the validity of the solution, and (iii) disaggregates specific commodities over carefully chosen arcs until a feasible and thus, optimal, solution to the original problem is found.

2 - Welfare-Maximizing Designs of Two-Tier Multi-Server Service Systems

Jing Yang Xi, University of California, Berkeley, Berkeley, CA, United States, Wai Kin (Victor) Chan

Heterogeneous servers are often adopted to accommodate customers with different delay sensitivities. A widely-used model is the two-tier *express system* where the first tier provides free regular service with slower servers and the second tier provides paid express service with faster servers, i.e., impatient customers can pay extra to reduce delay. We analyze the social welfare and welfare-maximizing price of such systems and propose a *reward system* where the second tier now provides rewards (charges negative toll) to attract patient customers; in terms of welfare, this is equivalent to charging higher prices for slower servers. We provide the conditions for when the reward system generates more welfare than the express system and vice versa. This duality—existence of two systems—requires the social planner to solve for the maximum welfare of both systems to maximize total market welfare. To complement our analytical analysis, we collect data on passengers to model the performance of the express and reward system in airport security check. Paradoxically, the free regular service in the reward system may have a lower waiting time than the paid express service in the express system, leading to higher utility for every passenger and higher welfare in the reward system.

3 - Heuristics using Consolidation Patterns for Increasing Solution Speeds of Service Network Design Problems using the Rolling Horizon Solution Method

Ryan Tramp, University of Alabama, Tuscaloosa, AL, United States, Nickolas Freeman

The service network design problem (SNDP) is an NP-hard networking problem that has proven to be computationally challenging in its most basic form. Thus, it is difficult to explore additional problem aspects, such as uncertainty in demand and order arrival, for all but very small instances. This research explores order consolidation patterns that emerge in optimal solutions to small SNDP instances and uses these insights to generate heuristics that can significantly reduce solution times while maintaining low gaps from optimality. An analysis of the optimal solution for small instances reveals that orders tend to consolidate around one of the locations where orders arrive at the network or order destinations depending on several factors. A major factor is the number of orders reaching a critical threshold that makes movement worthwhile. We encode common characteristics of solutions when the number of orders is around this threshold into our heuristics. Preliminary testing shows parity in solution qualities when comparing the heuristics to a rolling horizon approach that utilizes MIP models, with the heuristics offering significant reductions in computation time.

4 - Limiting Route Predictability using a Linear Approximation of Shannon Entropy

arvind rathore, University at Buffalo, Amherst, NY, United States, Robert Dell, Rajan Batta

This paper tackles route predictability by integrating unpredictability as a core driver of route design. We create a Multiple Patroller Math-heuristic based on traditional Mixed Integer Linear Programming (MILP) models that include a linear approximation of change in entropy as a constraint or an objective for improving entropy over subsequently generated route. Prior publications only utilize entropy for route selection. Applying our math-heuristic to a real-world scenario from the southeastern police district of Baltimore City, we discover a significant increase in entropy and coverage while maintaining a practical balance with a prize-collecting objective. We also develop cuts to improve solution time. The case study not only illustrates the viability of our model but also brings into focus its potential for widespread application in various secure routing contexts. We extend this work by demonstrating arrival time diversification, a common objective in Cash-in-Transit problems, and observe unpredictably scattered visit times with and without time windows.

Feedback and Information in Human-Algorithm Interactions

Invited Session

Behavioral Operations Management

Chair: Stephen Leider, University of Michigan, Ann Arbor, MI, United States

Co-Chair: Clare Snyder, Michigan Ross, Ann Arbor, MI, United States

1 - Algorithm Reliance for Binary Classification: Implications for Accuracy and Fairness

Clare Snyder, Michigan Ross, Ann Arbor, MI, United States, Samantha Keppler, Stephen Leider

In this research we use laboratory experiments to answer the question: how effective will binary classification algorithms designed for fairness (i.e., equal opportunity) be when they are channeled through a human decision-maker? The design of fair AI has received considerable attention in recent years, but another stream of research shows that people often under-rely on algorithms, even when these algorithms are proven to be highly accurate. It is therefore possible that when humans have ultimate decision authority, they will deviate from or ignore algorithms' advice in ways that undermine equal opportunity or other fairness outcomes. This may be particularly true for settings in which feedback is asymmetrically censored (e.g., loans, admissions, diagnoses) – where verification bias is present. In these settings, algorithms that achieve fairness by relaxing the threshold for one population may appear very different from algorithms that achieve fairness by doing the opposite, *even when the two algorithms are equally accurate.* Our results have implications for fair algorithm design.

2 - Warnings and Endorsements: Improving Human-AI Collaboration in the Presence of Outliers

Matthew DosSantos DiSorbo, Harvard Business School, Boston, MA, United States, Kris Ferreira, Maya Balakrishnan, Jordan Tong

1. Problem definition: While artificial intelligence (AI) algorithms may perform well on data that are representative of the training set (inliers), they may err when extrapolating on non-representative data (outliers). How can humans and algorithms work together to make better decisions when faced with outliers and inliers?

2. Methodology/results: We study a human-AI collaboration on prediction tasks using an anchor-and-adjust framework, and hypothesize that humans are biased towards naive adjustment behavior: making adjustments to algorithmic predictions that are too similar across inliers and outliers, when ideally adjustments should be larger on outliers. In an online lab experiment, we demonstrate that participants are indeed unable to sufficiently differentiate absolute adjustments to an AI algorithm when faced with both inliers and outliers, leading to a 143-176% increase in absolute deviation from the optimal prediction compared to participants who only face either all inliers or all outliers. We design a 'warning' ('endorsement') that alerts participants when feature values constitute outliers (inliers) and, in another experiment, we show that this warning (endorsement) helps participants differentiate adjustments, ultimately reducing absolute deviation from the optimal prediction by an

average of 35% (28%). However, we demonstrate that deploying both interventions together reduces participants' absolute deviation from the optimal prediction by 49%.

3. Managerial implications: Our work uncovers a behavioral bias towards naive adjustment behavior, and identifies a simple, educational intervention that mitigates this bias. Ultimately, we hope that this work will help managers best equip their employees with the knowledge they need to succeed in human-AI collaborations.

3 - Enhancing the Wisdom of Crowds when Experts use Algorithmic Advice

Angshuman Pal, Indiana University Kelley School of Business, Bloomington, IN, United States, Asa Palley, Ville Satopaa

In many managerial settings, good decision making depends on obtaining an accurate forecast of an uncertain variable of interest. Useful knowledge about the variable may be accessible to both human experts and AI models, where each may have their own relative advantages in forming an accurate forecast. To make use of both sources of information, AI advice can be provided to human experts who can assess how much weight it should be given when updating their prior forecasts.

Since useful information may be held by different individuals, combining forecasts from multiple experts can also boost the accuracy of the aggregate forecast. However, while providing AI advice to humans can be helpful at an individual level, it may also induce correlations in judgment errors that hamper efficient combination of information at the aggregate level.

Using a stylized Bayesian model of information held by human experts and the algorithm, we derive a new procedure for aggregating judgments when humans receive AI advice. The method uses individual responses to estimate how much weight to put on human versus AI forecasts, and forms an aggregate forecast by taking the final average human forecast and adjusting it toward or away from both the initial average human forecasts and the average AI advice.

4 - Productivity Implications of Working Side Jobs

Na Hyun Kim, University of Pennsylvania, Philadelphia, PA, United States, Park Sinchaisri

With the success of online platforms that utilize flexible forms of labor, it has never been easier to hold multiple jobs. However, research into such workers have been sparse namely due to difficulty in identification and heterogeneity of jobs to allow for an adequate comparison. We study a particular class of platform workers, medical professionals that work on third-party telehealth platforms, and mimic their work setting in an online game to measure productivity spillovers between the worker's main job and side job on said platform. We confirm our findings with surveys and interviews of such workers on a major telehealth platform in the US.

Advances in Queueing Theory

Invited Session

Applied Probability Society

Chair: Martin Zubeldia, University of Minnesota, Minneapolis, MN, United States

1 - Electrifying the Fleet: Non-Asymptotic Dimensioning of EV-Based Mobility Systems with Performance Guarantees

Saif Benjaafar, University of Michigan, Ann Arbor, MI, United States, Jingyuan Wan, Martin Zubeldia

We consider the problem of dimensioning an on-demand mobility service that relies on a fleet of electric vehicles and a dedicated charging infrastructure. We model the system as a closed queueing network and derive bounds on the minimal number of vehicles that guarantee a target availability and a charging capacity that guarantees that expected delay at the chargers does not exceed a target threshold. The bounds, which hold for any sized system, yield tight non-asymptotic dimensioning rules.

2 - Exponential Tail Bounds on Queues: a Confluence of Non-Asymptotic Heavy Traffic and Large Deviations

Siva Theja Maguluri, ISyE Georgia Tech, Atlanta, GA, United States, Prakirt Jhunjhunwala, Daniela Hurtado

Obtaining the exact steady-state distribution of queue lengths is not feasible in general. Therefore, we establish bounds for the tail probabilities of queue lengths. Specifically, we examine queueing systems under Heavy-Traffic (HT) conditions and provide exponentially decaying bounds for the probability $P(\epsilon q>x)$, where ϵ is the HT parameter denoting how far the load is from the maximum allowed load. Our bounds are not limited to asymptotic cases and are applicable even for finite values of ϵ, and they get sharper as $\epsilon\to 0$. Consequently, we derive non-asymptotic convergence rates for the tail probabilities. Unlike other approaches such as moment bounds based on drift arguments and bounds on Wasserstein distance using Stein's method, our method yields sharper tail bounds. Furthermore, our results offer bounds on the exponential rate of decay of the tail, which can be interpreted as non-asymptotic versions of Large Deviation (LD) results.

We demonstrate our approach by presenting tail bounds for a continuous time Join-the-shortest queue (JSQ) load balancing system. We not only bridge the gap between classical-HT and LD regimes but also explore the large system HT regimes, where the system size and the system load increase simultaneously. Our results also close a gap in the existing literature on the limiting distribution of JSQ in the super-NDS (a.k.a. super slowdown) regime. This contribution is of an independent interest. Here, a key ingredient is a more refined characterization of state space collapse for JSQ system, achieved by using an exponential Lyapunov function designed to approximate the sup norm.

3 - Matching Impatient and Heterogeneous Demand and Supply While Learning

Amy Ward, The University of Chicago Booth School of Business, Chicago, IL, United States, Weiliang Liu, Zhang Xun

We study a two-sided network where heterogeneous demand (customers) and heterogeneous supply (workers) arrive randomly over time to get matched. Customers and workers arrive with a randomly sampled patience time (also known as reneging time in the literature), and are lost if forced to wait longer than that time to be matched. The system dynamics depend on the matching policy, which determines when to match a particular customer class with a particular worker class. The issue in developing a matching policy is that model primitives are unknown. Our objective is to develop a policy that has small regret, where regret is the difference between the cumulative value of matches, minus costs incurred when demand and supply wait, between a proposed policy, that does not have knowledge of model primitives, and a benchmark policy, that does have full knowledge of model primitives. Our benchmark policy is an asympotically optimal policy (on fluid scale, as demand and supply rates grow large). A key challenge is that the benchmark policy depends on the patience time distributions, and may be different for different distributions, even when the mean is the same.

4 - Heavy-Traffic Optimality of Skip-the-Longest-Queue in Parallel Service Systems

Martin Zubeldia, University of Minnesota, Minneapolis, MN, United States

We consider a parallel service system consisting of a fixed number of single server queues, where a single stream of jobs arrive to it and need to be dispatched immediately upon arrival to one of the queues. For this setting, we propose a new dispatching policy dubbed Skip-the-Longest-Queue (SQL), where incoming jobs are sent to a queue that is not the longest one. We show that this policy is asymptotically optimal in heavy-traffic, even when the ID of the longest queue is only updated once every many arrivals.

Summit - 434

Probability on Networks

Invited Session

Applied Probability Society

Chair: Souvik Dhara, Purdue University, West Lafayette, IN, United States

1 - Convergence of Metropolis chains on large stochastic block models

SOUMIK PAL, University of Washington, Seattle, WA, United States, Siva Athreya, Raghav Somani, Raghav Tripathi

Metropolis Markov chains are commonly used to sample from dense random graph models. However, almost nothing is known about their rate of convergence to equilibrium. We consider the case when the size of the graph goes to infinity. In this regime, paths of a slightly modified Metropolis chain converges to a deterministic curve on the space of graphons. This curve is close to the gradient flow of the Hamiltonian on the metric space of graphons. A geometric analysis of this curve along this line leads to an exponential rate of convergence under a notion of convexity of the Hamiltonian.

2 - A Graph Limit Perspective on Sampling-Based GNNs

Yeganeh Alimohammadi, Stanford University, Stanford, CA, United States, Luana Ruiz, Amin Saberi

With the increasing size and complexity of graph data, scaling graph neural networks (GNNs) has become a crucial challenge. Over the past few years, many GNN training algorithms based on sampling have emerged to address this issue. In this talk, I will present a unified theoretical framework for training Graph Neural Networks on large input graphs using small, fixed-size sampled subgraphs. This framework is applicable to a wide range of models, including popular sampling-based GNNs such as GraphSAGE and FastGCN. Leveraging the theory of graph local limits, we demonstrate that, under mild assumptions, parameters learned from training sampling-based GNNs on small samples of a large input graph fall within an ϵ-neighborhood of the outcomes achieved by training the same architecture on the entire graph. We derive bounds on the number of samples, the size of the graph, and the training steps required as a function of ϵ. Our results provide a theoretical understanding of using sampling in training GNNs and suggest that by training GNNs on small samples of the input graph, practitioners can more efficiently identify and select the best models, hyperparameters, and sampling algorithms.

3 - Combining Rollout Designs and Clustering for Causal Inference with Network Interference

Mayleen Cortez, Cornell University, Ithaca, NY, United States, Matthew Eichhorn, Christina Yu

Estimating causal effects under *network interference* is pertinent to many real-world settings. However, the underlying interference network is often unknown to the practitioner, which precludes many existing techniques that leverage this fine-grained information. A recent line of work uses staggered rollout experimental designs, polynomial interpolation and low-order interaction models to obtain unbiased estimators *that require no network information*. However, the required polynomial extrapolation can lead to prohibitively high variance when the polynomial degree is higher than 1. In this work, we propose a two-stage staggered rollout experimental design that can use, but does not require, coarse-grained network knowledge to sub-sample the population and roll out treatment to a greater proportion of this sub-population. This greatly reduces variance from extrapolation, but at the cost of incurring some bias and sampling variance. Through numerical simulations, we explore the trade-off between the error attributable to the subsampling of our experimental design and the extrapolation of the estimator for both synthetic and real-world networks. We also present a general and explicit expression of the bias of the estimator under the proposed design as well as a bound on the variance. We find that when the degree is greater than 1, the proposed design greatly reduces error and outperforms against baseline estimators, especially when the treatment probability is small.

4 - Kernel and Graphical Methods for Conditional Inference

Bhaswar Bhattacharya, University of Pennsylvania, Philadelphia, PA, United States, Anirban Chatterjee, Ziang Niu

In this talk we will discuss methods for conditional nonparametric inference, such as conditional 2-sample and goodness-of-fit testing, using kernels and nearest-neighbor graphs. Leveraging ideas from nonparametric statistics and random geometric graphs, we will construct tests that can be readily applied to a range of problems, such as model calibration, regression curve evaluation, and validation of emulators in simulation-based inference.

Chang-Han Rhee session

Invited Session

Applied Probability Society

Chair: Chang-Han Rhee, Northwestern University, Evanston, IL, United States

1 - Higher-criticism for multi-sensor sparse change-point detection

Yao Xie, Georgia Institute of Technology, Atlanta, GA, United States, Tingnan Gong, Alon Kipnis

We present a procedure based on higher criticism (Dohono \& Jin 2004) to address the sparse multi-stream quickest change-point detection problem. Namely, we aim to detect a change in the distribution of the multi-stream that might occur in some unknown time instant. The change itself, if occurs, only affecting a few data streams out of potentially many while those affected streams, if exist, are unknown to us in advance. Our procedure involves testing for a change point in individual streams and combining multiple tests using higher criticism. As a by-product, our procedure also indicates a set of streams suspected to be affected by the change. We characterize the information-theoretic detection limit under a Gaussian heteroscedastic mean shift when individual tests are based on the LR or GLR and show that our procedure attains this limit; this limit coincides with existing results in the homoscedastic case. We demonstrate the effectiveness of our method compared to other procedures using numerical evaluations.

2 - DPZero: Private Fine-Tuning of Language Models without Backpropagation

Sewoong Oh, University of Washington, Seattle, WA, United States

The widespread practice of fine-tuning large language models (LLMs) on domain-specific data faces two major challenges in memory and privacy. First, as the size of LLMs continues to grow, the memory demands of gradient-based training methods via backpropagation become prohibitively high. Second, given the tendency of LLMs to memorize training data, it is important to protect potentially sensitive information in the fine-tuning data from being regurgitated. Zeroth-order methods, which rely solely on forward passes, substantially reduce memory consumption during training. However, directly combining them with standard differentially private gradient descent suffers more as model size grows. To bridge this gap, we introduce DPZero, a novel private zeroth-order algorithm with nearly dimension-independent rates. The memory efficiency of DPZero is demonstrated in privately fine-tuning RoBERTa and OPT on several downstream tasks.

3 - Diffusion Models for Generative Optimization via High-Dimensional Modeling

Minshuo Chen, Northwestern University, Evanston, IL, United States

Deep generative AI, e.g., diffusion models, achieves state-of-the-art performance in various high-dimensional data modeling tasks. Such empirical successes have been challenging conventional wisdom. In this talk, we will focus on diffusion models to explore their methodology and theory. We will first understand how diffusion models efficiently model complex high-dimensional data, especially when there are low-dimensional structures in them. Then, we leverage our understanding of diffusion models to motivate a next-generation optimization method, termed “generative optimization”. Specifically, we utilize diffusion models as a data-driven solution generator to an unknown objective function. We propose a learning-labeling-generating algorithm incorporating the targeted function value as guidance to the diffusion model. Theoretically, we show that in the offline setting, the generated solutions yield large function values on average. Meanwhile, the generated solutions closely respect the data intrinsic structures in the training set. Empirically, we demonstrate a good synergy of generative optimization with reinforcement learning.

4 - Accelerating diffusion models with stochastic Runge-Kutta method

Yuchen Wu, University of Pennsylvania, Philadelphia, PA, United States

In this talk, I will present a new framework for accelerating diffusion models using the stochastic Runge-Kutta method. Our approach is different from the previous acceleration methods, and offers an improved theoretical guarantee. Numerical experiments confirm the practicality of our approach.

Emergency Services Efficiency and Workload Balance

Contributed Session

Chair: Jenna Ercolani, Wichita State University, 1845 Fairmount St, Wichita, KS, 67260, United States

1 - A Dynamic Programming Approach to Balancing Workload in EMS Through Intra-Shift Crew Swapping

Setareh Darvishi, Wichita State University, Wichita, KS, United States, Laila Cure

This project develops an optimization model for reassigning ambulance crews to different stations at different points in time throughout a shift to balance their workload. The collaborating Emergency Medical Services (EMS) system currently assigns crews to stations for a full 12-hour shift. These fixed assignments often result in an imbalanced workload among crews given that demands at different locations can be significantly different, even during the same shift. We propose a stochastic dynamic programming formulation in which the state of the system at each decision epoch is described by the current station assignment and cumulative workload of all crews in the system. The proposed state information can be extracted in real time from dispatch data commonly available to EMS systems and the main source of uncertainty is the random nature of 9-1-1 calls. The optimal policy aims at minimizing the expected total cost. The terminal cost function measures the disparity in the expected terminal workload of all crews and the intermediate cost function represents the undesirable aspects of swapping. The applicability of the proposed strategy and the effectiveness of the model will be evaluated using data from Sedgwick County EMS.

2 - Spatiotemporal Analysis of Volunteer First Responders Effectiveness

Michael Khalemsky, Hadassah Academic College, Jerusalem, Israel, Janna Ataiants, Stephen Lankenau, Anna Khalemsky, Alexis Roth, Gabriela Marcu, David Schwartz

Rapid first aid is vital for reducing mortality and improving long-term prognosis during medical emergencies. One approach to achieving faster response times is through smartphone-based Volunteer First Responder (VFR) networks. VFR effectiveness is measured by factors such as arrival time, relevant intervention, and medical outcomes. Geographic coverage is a commonly used measure of emergency medical service effectiveness. This study presents a novel analytical technique for analyzing VFR network effectiveness in terms of geographic coverage using real-world data from a field study. The analysis considers the unpredictable location and availability of VFRs during an emergency event, aiding decision-making for recruitment and retention efforts and improving collaboration with EMS. Findings can enhance VFR network administrators' efforts to save lives.

3 - Optimizing Police Staffing Allocation Using Data Envelopment Analysis

Andrew Hall, Marymount University, Arlington, VA, United States, Erik Alda

Efficiently allocating police personnel to match workload demands is a critical challenge facing law enforcement agencies nationwide (Wilson & Weiss, 2014). Understaffed departments struggle with slow response times, officer safety risks, and reduced community engagement, while overstaffing wastes limited resources (Wilson & Grammich, 2012; Chalfin & McCrary, 2018). The uneven distribution of crime and calls for service within jurisdictions further complicates staffing decisions (Wu & Murray, 2005; Wheeler, 2022). Traditional staffing models based on population ratios or historical precedent often fail to capture the dynamic, place-specific nature of police workload (Wilson & Weiss, 2012). This can result in the overpolicing of some communities and the underprotection of others (Kennedy, 1997; Mastrofski, 2004). Inequitable deployment hinders police effectiveness and undermines police legitimacy and community trust (Rosenbaum & Schuck, 2012). The purpose of this study is to optimize the deployment of a small city police patrol resources in using frontier methods and its variants. Working on a research-practitioner partnership between the police department and Marymount University, we develop, implement, and evaluate a data-driven staffing allocation model that enhances the efficiency and equity of police services. We will develop a data envelopment analysis (DEA) model by integrating data on labor, capital, and outputs produced. Various efficiency models, including traditional DEA and advanced variations like inverse data envelopment analysis (efficiency-based model), Malmquist-Luemberger Index, and partial frontier models, will be used to assess efficiency. We also implement changes to police allocation based on the efficiency model results.

4 - Physics-Based Surrogate Model Development for Prediction of Crew Member Workload in Emergency Medical Services

Jenna Ercolani, Wichita State University, Wichita, KS, United States

Workload in Emergency Medical Services (EMS) has been historically measured by metrics such as call volume or Unit Hour Utilization (UHU). This paper investigates a physics-based surrogate model to calculate a measure of an EMS crew member’s utilization more accurately, considering indirect work tasks, such as documentation time and shift start activities. The true measure of utilization was based on a trace-based simulation output incorporating VACP (Visual, Auditory, Cognitive, Psychomotor) workload measures built with real-world data and estimates for indirect work. The constructed surrogate models, and conventional measures of workload were tested against the simulation outputs for a years’ worth of data. Root mean square error (RSME), symmetric mean absolute percent error (sMAPE), and Pearson correlation estimates were used to compare models. The model with the optimal metrics included shift start time and a call duration estimate including averages of driving to post time, documentation time, and call response time. The optimal model was tested using sensitivity analysis and uncertainty calculation. General models were given for use in other EMS systems.

Empirical Healthcare Operations

Invited Session

Health Applications Society

Chair: Zahra Mobini, Georgia Tech, Atlanta, GA, United States

Co-Chair: Wilson Lin, Santa Clara University, Santa Clara, CA

1 - Promoting Generics: Effects on Pharmaceutical Quality

In Joon Noh, Korea University, Seoul, Korea, Republic of, Hessam Bavafa, Christian Blanco

Generic drugs are a cornerstone of affordable healthcare. We examine the pharmaceutical quality effects of the Generic Drug User Fee Amendments (GDUFA), a hallmark legislation enacted by Congress in 2012 that armed the FDA with resources to improve the timeliness of generic drug application reviews. GDUFA succeeded in shortening the total application review time, which includes waiting time, from a median of 44 to 14 months. We find, however, that generic drugs approved after GDUFA have 28.6% higher recall rates. We show that this effect has been persistent since the second year of the law’s implementation, and that the increase in recall rates was driven by manufacturing-related deficiencies, specifically, contamination issues. We also investigate heterogeneity by recall severity and find that the increase in recalls after GDUFA is driven by severe (Class I and II) recalls. These findings inform previously unquantified quality reductions stemming from the policy promoting generic drugs.

2 - The Role of Physician Integration in Alternative Payment Models: The Case of The Comprehensive Joint Replacement Program

Kraig Delana, IE Business School, Madrid, Spain, Christopher Chen

U.S. physicians are increasingly unifying (both horizontally and vertically) while transitioning from fee-for-service to alternative payment models. We empirically examine the role of both horizontal and vertical integration of orthopaedic surgeons in driving heterogeneity in the impact of the Comprehensive Joint Replacement (CJR) alternative payment program. We find CJR hospitals with high horizontal and vertical integration see an increase in both hospital costs and risk-adjusted complication rates of 3.17% & 1.18, respectively. Moreover, we present evidence showing integration affects physician care decisions regarding length-of-stay and discharge disposition which explains the changes in hospital payments. Our findings provide novel insights into provider integration and clinical decisions that are relevant for policymakers, payors, and healthcare providers.

3 - Budget Blues in Healthcare: Unveiling the True Impact of Maryland's Hospital Payment Reform

Zahra Mobini, Georgia Tech, Atlanta, GA, United States, John McCandlish, Turgay Ayer

To rein in healthcare costs, Maryland implemented a global budget program (GBP) for its hospitals, establishing yearly cost growth targets for all inpatient and outpatient services. Leveraging an extensive claims dataset for commercially insured individuals, our study empirically examines how the GBP influences care delivery patterns within hospitals.

4 - Valuing Nursing Productivity in Emergency Departments

Sokol Tushe, University of South Florida, Tampa, FL, United States, Hao Ding, Diwas KC, Donald Lee

The United States is over a decade into the worst nursing shortage crisis in history, fueled by chronic underinvestment. To demonstrate to hospital managers and policymakers the benefits of investing in nursing, we clarify the positive downstream effects of doing so in the ED setting. We use a high-resolution data set of patient visits to the ED of a major U.S. academic hospital. Time-dependent hazard estimation methods (nonparametric and parametric) are used to study how the realtime service speed of a patient varies with the state of the ED, including the time-varying workloads of the assigned nurse. A counterfactual simulation is used to estimate the gains from increasing nurse staff in the ED. We find that lightening a nurse’s workload by one patient is associated with a 14% service speedup for every patient under the nurse’s care. Simulation studies suggest that adding one more nurse to the busiest 12-hour shift of each day can shorten stays and avert $160,000 in lost patient wages per 10,000 visits. The reduction in service times also frees up capacity for treating more patients and generates $470,000 in additional net revenues for the hospital per 10,000 visits. Extensive sensitivity analyses suggest that our key message—investing in nursing will more than pay for itself—is likely to hold across a wide range of EDs.

1 - Enhancing Cost-Effectiveness of Screening for Chronic Obstructive Pulmonary Disease (COPD) with Smoking Cessation Interventions in China: A Simulation Modeling Study

Qiushi Chen, Penn State University, University Park, PA, United States, Yiwen Fan, Simiao Chen

China has the highest mortality rate from chronic obstructive pulmonary disease (COPD) in the world. Previous studies have shown the cost-effectiveness of COPD screening for the general population in China. Considering that smoking is the most common risk factor for COPD burden in the country, in this study, we aim to explore the impact of adding smoking cessation interventions following the screening to further enhance the management of COPD. We develop a microsimulation model and calibrate it to the estimates of the disease epidemiology and smoking behaviors in China. Using the calibrated simulation model, we evaluate multiple follow-up smoking cessation interventions by different intensities, including minimal counseling (counseling <90 min), intensive counseling (counseling >=90 min), and pharmacotherapy, and compare with screening only without cessation interventions. We find that all smoking cessation interventions are highly cost-effective and can further reduce exacerbations and deaths from COPD.

2 - Improving Vascular Access Outcome in Hemodialysis Considering Frailty: A Microsimulation Approach

Yiwen Cao, University of Southern California, Los Angeles, CA, United States, Sze-chuan Suen, Eugene Lin, Karen Woo, Mariana Murea

In hemodialysis, the choice of vascular access (catheter, arteriovenous [AV] fistula, or AV graft) influences maturation duration, length of functional usage, complication rates, and expected lifespan. While clinical guidelines generally recommend using AV fistulas, variation in patient physiologic function -- specifically frailty levels -- necessitates a more personalized recommendation for vascular access. With a team of clinicians, we developed a microsimulation model to evaluate the short-term and lifetime effects of different vascular access types on hemodialysis outcomes. Due to limited data directly relating to frailty, we employed various methods to estimate its impact on patient outcomes. We derived relative risks associated with access maturation from national prevalence data and existing literature and applied a risk multiplier to access failure using age as an indirect indicator, thereby simulating the impact of frailty. We observed the performance differences across vascular access choices and captured expected health outcomes with respect to patient characteristics including frailty and age. As multiple failures of vascular access are common in hemodialysis, we allowed for repeated decisions of vascular access choice when previous access failed in the model. We therefore stratified the model inputs by the number of prior failures and performed scenario analyses to provide cohort-specific recommendations for vascular access choice.

3 - Calibration of Simulated Organ Allocation Models Using Conformal Prediction Concepts

Hyunwoo Shin, Virginia Tech, Blacksburg, VA, United States, Sait Tunc, Xi Chen

Simulation models have played a crucial role in evaluating the effectiveness of organ allocation policies. However, traditional validation methods such as hypothesis testing and confidence intervals often fall short, primarily due to the limited and non-stationary nature of the transplantation data, compounded by the variability of p-values across simulation replications. Notably, p-values can exhibit significant variation even within the same model, depending on the number of outputs, thereby highlighting inconsistencies in traditional statistical testing. To address these challenges, our study introduces a novel approach inspired by the principles of conformal prediction. This method estimates the relative location of original data when presented with simulated data, offering a robust alternative to conventional tests. By adapting conformal prediction concepts, we provide a solution that enhances the calibration of simulation models and increases the reliability of their results, thereby supporting better-informed decision-making in organ allocation policies.

4 - Managing Cargo Drones for Health Product Delivery

Boas Meijer, INSEAD, Fontainebleau, France, Stephen Chick, Prashant Yadav

Drones are increasingly used for the last-mile delivery of health products. The value of drones as an alternative delivery method lies in their ability to respond quickly to medical emergencies. They also provide an efficient alternative to ground transport for less urgent replenishments of certain products, and in certain geographies. In this research, we study a drone service provider's decision on how to set its drone capacity, and schedule its drones in light of these two use cases. More specifically, we assume the decision maker takes into account differences between incoming orders for drone transport in terms of responsiveness needs, and delivery time. We establish and evaluate control policies to get a better sense of the tradeoff between responsiveness and capacity in this setting, and different levels of resource sharing can mitigate this tradeoff. Our models are calibrated using data on existing drone operations from our industry partner.

Precision in Practice: Data Insights in Healthcare Management

Invited Session

Health Applications Society

Chair: Jacob Jameson, Harvard University, Cambridge, MA, United States

1 - Variation in Batch Ordering of Imaging Tests in the Emergency Department and the Impact on Care Delivery

Jacob Jameson, Harvard University, Cambridge, MA, United States, Soroush Saghafian, Robert Huckman, Nicole Hodgson

We use practice variation across physicians to uncover the role of test-ordering on care delivery in the ED. Using records of over 45,000 Mayo Clinic emergency department visits, we find that quasi-random assignment to a top (versus bottom) decile batching physician significantly increases excess diagnostic testing. Instrumental variable results show that batching leads to an additional 13.5 tests per 100 batches, resulting in excess tests that would not have been ordered under a sequential-ordering strategy. Contrary to expectations, batch ordering does not reduce ED length of stay or affect 72-hour return rates, challenging the perceived efficiency of batching and highlighting the necessity for more targeted testing strategies in emergency care.

2 - Mathematical models for cancer decision-making considering healthcare system and access constraints

Melissa Franco, Stanford, Stanford, CA, United States

Decision-makers in resourced-constrained settings face a unique barrier in implementing cancer control policies that reduce the time from symptom presentation to diagnosis and treatment to improve cancer outcomes. Mathematical modeling has increasingly been used to inform cancer control policy decisions; however, most modeling analyses are commonly tailored for more developed healthcare systems. These analyses overlook capacity constraints, which may bias the achievable impact of cancer health interventions and policies. The central component of this project will be to critically illustrate how ignoring or changing capacity constraints in mathematical models will impact cancer outcomes and, ultimately, healthcare decision-making. We developed a general modeling cancer framework with three capacity constraints along the cancer continuum (screening, diagnosis, and treatment). Then, we applied this framework to breast cancer healthcare constraints in Mexico and the United States.

3 - Effective and Efficient Staff in Emergency Departments

Hossein Hejazian, Harvard University, Cambridge, MA, United States, Soroush Saghafian

Emergency Departments (EDs) are complex, complicated, and always congested. Despite the extensive literature on ED operations, it is still an open question who constitutes an effective and/or efficient ED staff. This question is crucial in forming care teams to achieve the highest efficiency of the ED. We use a data set of ED visits in a leading US hospital to study the challenge of evaluating ED staff performance. Our aim is to propose a metric that combines the different aspects of a staff's productivity and the quality of delivered care. We investigate how various combinations of ED staff can impact operational efficiency and patient outcomes. Additionally, we analyze the potential peer effects among the ED staff. Our ultimate goal is to help our partner hospital attain higher efficiency levels by improving the formation of care teams (attending, nurses, residents, etc.) in their ED through a better understanding of the inherent trade-offs.

Innovative Strategies for Efficient and Sustainable Systems

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Yunlong Peng, University of Warwick- Warwick Business School, Coventry, United Kingdom

1 - Discriminatory Pricing in Queuing Systems: The Curse of Non-Transparency

Zihao Chen, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Xingyu Fu, Ying-Ju Chen

We study the pricing decision of a server within a queuing system. The server can differentiate between high-valuation consumers and low-valuation consumers and can implement discriminatory pricing. Surprisingly, we find that when congestion is at an intermediate level, price discrimination can harm the server's profitability. This unexpected outcome stems from the fact that discriminatory pricing results in a lack of transparency regarding prices, causing high-valuation consumers to distrust the server's promise to serve them exclusively. In other words, it is hard for the server to resist the temptation/opportunism to secretly include low-valuation consumers. As a result, high-valuation consumers' motivation to make purchases is dampened. To address these concerns, the server needs to lower prices to attract high-valuation customers, thereby reducing the server's profit margin. We demonstrate that the preemptive prioritization of high-valuation consumers can serve as a credible commitment mechanism and effectively address the non-transparency issue related to discriminatory pricing in queuing systems.

2 - Crowdsourcing Electric Mobility for Omni-Sharing Distributed Energy Resources

Wenqing Ai, University of Science and Technology Beijing, Beijing, China, People's Republic of, Tianhu Deng, Wei Qi

Ever-increasing coupling of energy and mobility sectors is underway in our cities. However, whether and how to use such coupling to optimize the portfolio and operations of urban energy assets has rarely been studied. We fill this gap by studying “omni-sharing,” which is a novel business model (beyond “peer-to-peer” energy sharing) that allows a distributed energy resource (DER) community to crowdsource electricity from shared electric vehicles (EVs). We analytically model two salient features of omni-sharing operations: the optimal payment to crowdsourced EV drivers, and the cost allocation among internal DERs. In doing so, we enrich the existing newsvendor cooperative game theory results by generalizing the newsvendor model with a variable underage cost structure, induced by the endogeneity of the energy-crowdsourcing cost. We prove (and quantify with data on residential energy consumption and ride-sharing markets) that omni-sharing can reduce the total storage capacity needed and the expected energy cost for the DER community. To account for intra-day energy demand fluctuation and supply uncertainty, we also develop a real-time dispatch model. Our analysis shows the value of omni-sharing as an additional channel of efficiently matching local energy supply and demand. Omni-sharing exerts mixed (but on balance positive) externalities: positive effects on ride-share drivers, and moderate and reducible negative effects on ride-share passengers and platforms. Moreover, omni-sharing enhances the urban grid’s self-sufficiency in terms of both peak load reduction and ramping mitigation. This paper strengthens our understanding of energy-mobility orchestration toward enabling smart cities.

3 - Harnessing Collective Wisdom: Crowd Judging in Enhancing Dispute Resolution on Two-Sided Platforms

Chong Zhang, Tilburg University, Tilburg, Netherlands, Zhonghong Kuang

Emerging digital platforms are introducing innovative mechanisms for resolving disputes by leveraging crowd judging as an alternative to traditional adjudication systems. This study investigates the effectiveness of crowd judging in improving dispute resolution on two-sided platforms, particularly in scenarios involving meticulous reviews and fastidious customers. We develop a game-theoretic model in which sellers can either present evidence proving their innocence or introduce misleading information to sway judges. By comparing conventional platform-based adjudication with the crowd judging mechanism, we aim to determine if the latter offers superior market efficiency and increased sellers' profits. Additionally, we explore the impact of information sharing among judges on the efficiency of the crowd judging process, assessing its potential to enhance decision-making accuracy.

4 - Assortment Personalization in A Subscription Model

Jiannan Xu, Robert H. Smith School of Business, University of Maryland, College Park, MD, United States, Gah-Yi Ban, Wedad Elmaghraby, Beril Toktay

We investigate the assortment personalization problem in a subscription model. Specifically, this paper focuses on a clothing rental subscription model where customers can rent clothes from a personalized closet of designer brands. We incorporate product fit uncertainty, i.e. the uncertainty surrounding how the customers will ``feel'' once they receive the garments and wear them into the subscription decision model, and consider nested constraints, i.e. that the firm’s decision is subject to the assortment cardinality constraint and the customer’s choice is subject to the subscription basket constraint, in the assortment personalization problem. We address how firms should select an optimal assortment considering (1) the product fit uncertainty and (2) the nested constraints to maximize expected lifetime revenue from a customer; we call this the doubly combinatorial assortment personalization problem. We show that this problem is NP-hard. Analytically, we derive optimal results for special cases and come up with near-optimal approximations for general cases with binding constraints. Computationally, our experiments on randomly generated instances demonstrate that our approximation algorithms, on average, yield expected revenues that are within 2.6% of the optimal expected revenue. Finally, we derive insights on how subscription service providers can optimize assortments by thinking products as functions of signal-to-noise ratios.

Scheduling of Manufacturing and Service Processes

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Norbert Trautmann, University of Bern, FM Quantitative Methoden, Bern, 3012, Switzerland

1 - Online Quotation Under Delayed Customer Feedback and Offline Production Scheduling

Kelvin Ekun, University of Massachusetts, Amherst, MA, United States, Ana Muriel

While make-to-order (MTO) manufacturers provide order quotations upon request and may face penalties for not meeting the promised lead times, customers are typically offered a grace period over which to make the final decision to place their quoted order. As a result, the MTO firm faces an online lead time quotation problem with delayed feedback on order acceptance. The shorter the quoted lead time, the higher the probability of acceptance. Meanwhile, the production department will optimize and set the production schedule offline at regular intervals, given the current firm orders. We propose a primal-dual algorithm for this online quotation problem with delayed feedback and the periodic offline scheduling objective is to maximize total profit penalized by tardiness costs. Using simulation-based experiments, we show the performance of the proposed method relative to a hindsight oracle and show that it outperforms benchmarks used in practice.

2 - Flow Shops with Reentry: Total Completion TIME Optimal Schedules

Nicklas Klein, University of Bern, Bern, Switzerland, Michael Pinedo

Flow shops are widely studied machine environments in which all jobs must visit all machines in the same order. While conventional flow shops assume that each job traverses the shop only once, many industrial environments require jobs to pass through the shop multiple times before completion, i.e., after traversing the shop and completing its processing on the last machine, a job must return to the first machine and traverse the shop again until it has completed all its required loops. There are numerous applications, e.g., in semiconductor manufacturing, of such a setting, which is called a flow shop with reentry. The planning problem is to schedule all loops of all jobs while minimizing the total (weighted) completion time. We consider a reentrant flow shop with unit processing times and show that the Least Remaining Loops First (LRL) priority rule minimizes the total completion time. Furthermore, we show that the problem of minimizing the total weighted completion time is NP-hard. For this objective, we show that the Weighted Least Remaining Loops First (WLRL) priority rule has a worst-case performance ratio of about 1.2.

3 - A Hybrid Column Generation and Constraint Programming Approach for the Multi-Project Scheduling Problem with Local Resources

Maximilian Kolter, Technical University of Munich, Munich, Germany, Chris Beck, Rainer Kolisch, Martin Grunow

This research tackles the multi-mode resource-constrained multi-project scheduling problem with global and local resources. Global resources are shared among projects, and local resources belong to a specific project. While many heuristic algorithms exist for this problem, exact approaches for large-scale instances are missing. Hence, we propose an exact branch-and-price algorithm. Our algorithm is based on a reformulation of the classical discrete-time formulation. The reformulation allows the decomposition of the problem by projects and gives tighter linear relaxations than the classical formulation. However, the reformulated problem requires a huge number of variables. Thus, we solve the linear relaxations of the reformulated problem via column generation. The resulting pricing problems are NP-hard scheduling problems, which we solve via constraint programming. We validate the effectiveness of our algorithm benchmarking against commercial integer programming and constraint programming solvers.

4 - Workload Balancing in Integer Programming Models for Project Scheduling

Norbert Trautmann, University of Bern, Bern, Switzerland, Nina Ackermann, Tamara Bigler

A single-item or small-series production environment can be represented as a project consisting of a set of precedence-related activities that require time and resources to be performed. The resources represent, for example, production personnel. We present a mixed binary linear program for minimizing the makespan subject to workload balancing constraints.

Summit - 442

Stochastic Models for Healthcare Operations

Invited Session

MSOM: Healthcare

Chair: Vahid Sarhangian, University of Toronto, Toronto, ON, Canada

Co-Chair: Jangwon Park, University of Toronto, Toronto, ON, Canada

1 - Mitigating Nurse Shortage via Inter-Hospital Nurse Transfers: a Sample Robust Optimization Approach

Mengshi Lu, Purdue University, West Lafayette, IN, United States, Wei Liu, Tianchun Li, Pengyi Shi

We consider a nurse transfer problem that involves moving nurses from hospitals with surpluses to hospitals with shortages, thereby matching the demand and supply at each hospital. Specifically, we consider a fully connected network, allowing transfers between any two hospitals. Transferred nurses might need to stay at the destination hospital for a few days, known as secondment, to avoid long commutes. Additionally, the nurses need to receive advance notice of their transfers. However, a demand shift from the historical sample path—caused, for example, by the rapid spread of COVID-19 and the statewide distribution of hospitals—makes planning these transfers challenging. To address this, we adopt a sample robust optimization (SRO) approach. However, due to its complexity, this is challenging to solve. To simplify, we reformulate the problem into a more manageable linear optimization problem using linear decision rules. We show that the network design has a more significant impact on reducing total costs, and other related metrics including the transfer volumes and transfer distances compared to the secondment scenarios and the methods applied (SAA and SRO). Furthermore, our analysis reveals that longer secondments notably reduce these metrics as well. Moreover, we show that the SRO strategy is preferable in contexts where increases in nurse demand are anticipated, as it effectively minimizes the necessity for emergency transfers. This underscores the importance of considering a fully connected network design, secondments, and the SRO approach to enhance cost efficiency, minimize emergency transfers, and improve the system's responsiveness to demand fluctuations.

2 - Early Birds Versus Last-Minute Arrivals: Empirical Evidence and Theoretical Analysis of Arrival TIME Queueing Game

Xiangjie Zhao, Shanghai University of Finance and Economics, Shanghai, China, People's Republic of, Yichuan Ding, Dongdong Ge, xiaoqing xie

In this study, we examine a scenario where each customer strategically selects their arrival times at a queue, aiming to minimize their total costs, which include waiting, tardiness, and earliness costs. Building on the mixed strategy framework characterized by Haviv (2013), which provides a closed-form arrival time distribution, our focus extends to the transient behavior of this system in presence of irrational customers, in which case it is not yet known whether an equilibrium exists or whether the system would converge to the equilibrium. We introduce a dynamic choice model to describe customers' behavior in a repeated game setting. We empirically validate this model using data from a large endoscopy clinic in China, operating on a first-come-first-served basis. The empirical result supports the efficacy of this dynamic choice model in capturing the adaptive strategies of patients concerning their arrival times. Leveraging this model, we prove that there exists a unique equilibrium and the system converges to this equilibrium under both the fluid model and the M/M/1 queue model. Furthermore, we formulate a dynamic control problem to characterize the optimal information sharing policy, suggesting that service providers may decrease social cost by deliberately modulating the communication of waiting time information to patients. Further examination of social cost unveils that increasing earliness cost can, counter-intuitively, detract from social cost at equilibrium.

3 - Mass Vaccination Scheduling: Trading off Infections, Throughput, and Overtime

Shanshan Luo, UBC Sauder School of Business, Vancouver, BC, Canada, Steven Shechter

Mass vaccination is essential for epidemic control, but long queues can increase infection risk. We focus on scheduling arrivals at mass vaccination sites to minimize a tri-objective function of infection risk, throughput, and overtime. Leveraging multi-modularity results from a related optimization problem, we construct a solution algorithm and find that our model-based policy significantly outperforms an equally-distributed, equally-spaced schedule. We also discuss managerial insights regarding the optimal schedule's structure and compare it to the well-known "dome-shaped" policies in appointment scheduling problems.

Summit - 443

Recent Advances in Data-Driven Decision-Making

Invited Session

MSOM: Service Operations

Chair: Hamsa Bastani, Wharton School, Philadelphia, PA, United States

Co-Chair: Stefanos Poulidis, INSEAD, Fontainebleau, 77300, France

1 - Transfer Learning Through Directional Gradients

Vishal Gupta, University of Southern California, Los Angeles, CA, United States

We propose a novel decision-aware approach for multitask learning (data-pooling) tailored to low-data environments. Our approach is flexible and general purpose. The key idea is to leverage zeroth order directional gradients to estimate out-of-sample performance of particular pooled policies. For well-behaved policies, these directional gradient estimates are themselves differentiable and can be (approximately) optimized via SGD. Our method provably identifies best-in-class policies and performs well on real data with minimal tuning.

2 - Contextual Linear Optimization with Bandit Feedback

YICHUN HU, Cornell University, Ithaca, NY, United States, Nathan Kallus, Xiaojie Mao, Yanchen Wu

Contextual linear optimization (CLO) uses predictive observations to reduce uncertainty in random cost coefficients and improve performance. An example is stochastic shortest path with random edge costs. Existing work on CLO focuses on data with fully observed cost coefficient vectors, but in many applications we can only see the realized cost of a historical decision, that is, just one projection of the random cost coefficient vector. We study a class of algorithms for CLO with this so-called bandit feedback which we term induced empirical risk minimization (IERM), where we fit the predictive model to directly optimize downstream performance of the policy it induces. We show a fast-rate regret bound for IERM that allows for misspecified model classes and flexible choices of the optimization estimate, and we develop computationally tractable convex relaxations. We further demonstrate and compare the performance of different modeling choices numerically using a stochastic shortest path example, and provide practical insights from our empirical results.

3 - Quantifying the Cost of Learning in Queueing Systems

Wentao Weng, MIT, Cambridge, MA, United States, Daniel Freund, Thodoris Lykouris

Queueing systems are widely applicable stochastic models with use cases in communication networks, healthcare, service systems, etc. Although their optimal control has been extensively studied, most existing approaches assume perfect knowledge of the system parameters. This assumption rarely holds in practice where there is parameter uncertainty, thus motivating a recent line of work on bandit learning for queueing systems. This nascent stream of research focuses on the asymptotic performance of the proposed algorithms.

In this work, we argue that an asymptotic metric, which focuses on late-stage performance, is insufficient to capture the intrinsic statistical complexity of learning in queueing systems which typically occurs in the early stage. Instead, we propose the \emph{Cost of Learning in Queueing (CLQ)}, a new metric that quantifies the maximum increase in time-averaged queue length caused by parameter uncertainty. We characterize the \textsc{CLQ} of a single-queue multi-server system, and then extend these results to multi-queue multi-server systems and networks of queues. In establishing our results, we propose a unified analysis framework for \textsc{CLQ} that bridges Lyapunov and bandit analysis, provides guarantees for a wide range of algorithms, and could be of independent interest.

4 - Aligning Model Properties via Conformal Risk Control

William Overman, Stanford University, Stanford, CA, United States, Jacqueline Vallon, Mohsen Bayati

AI model alignment is crucial in modern machine learning due to the underspecified pipeline where numerous models with excellent test set metrics may not meet end-user requirements. Recent advances show that post-training model alignment via human feedback can address some of these challenges. However, these methods are often limited to settings like generative AI where humans can interpret model outputs and provide feedback. In traditional non-generative settings, where model outputs are numerical values or classes, detecting misalignment through single-sample outputs is more challenging.

We consider an alternative strategy. We propose interpreting model alignment through property testing, defining an aligned model as one belonging to a subset of functions that exhibit specific desired behaviors. We focus on post-processing a pre-trained model to better align with this subset using conformal risk control. Specifically, we develop a general procedure for converting queries for a given property to a collection of loss functions suitable for use in a conformal risk control algorithm. We prove a probabilistic guarantee that the resulting conformal interval around the model contains a function approximately satisfying the desired property. We exhibit our methodology on a collection of supervised learning datasets and for a variety of properties such as monotonicity and concavity. The general procedure is flexible and can be applied to a wide range of desired properties.

Summit - 444

Leveraging AI in Behavioral and Service Operations

Invited Session

MSOM: Service Operations

Chair: Paige Tsai, Harvard Business School, Somerville, United States

Co-Chair: Ryan Buell, Harvard Business School, Boston, MA, United States

1 - Dynamic Scripting in Call Center Operations

Michelle Kinch, Tuck School of Business at Dartmouth College, Hanover, NH, United States

Artificial intelligence is being rapidly deployed to change the face of customer service operations. In this study, we examine efficiency-service tradeoffs when AI is used to reinforce service script protocols used by call center agents.

2 - How Prediction Intervals Improve Human Algorithm Collaboration

Chantale Köster, University of Cologne, Cologne, Germany, Cedric Lehmann, Andreas Fuegener, Ulrich Thonemann

For managerial decision tasks, humans and algorithms often work together with the intention to combine their skills and thereby achieve complementary performance, that is, a higher performance than either party could achieve on their own. Data from practice and research suggests that algorithmic advice often improves human decisions, however, not beyond the algorithmic performance. Trust calibration due to missing collaboration mechanisms are seen as the main reason for unexploited complementary performance potential. One potential collaboration mechanism is to communicate algorithmic certainty. In this paper, we analyze how human decision making in algorithmically supported tasks is affected by the provision of prediction intervals. In a laboratory experiment, participants worked on a forecasting task in which they and the algorithmic advisor had complementary information. We show that prediction intervals are an effective mechanism that improve trust calibration. This way, decision makers rely more on accurate advice that comes with high certainty and less on inaccurate advice that comes with low certainty, leading to a higher complementary performance outperforming both - humans and algorithms - working alone. Our results contribute to a better understanding of how humans and algorithms can achieve complementary performance. We suggest that managers consider the provision of prediction intervals in algorithmically supported decision making, since they lead decision makers to efficiently use algorithmic advice and achieve complementary performance.

3 - Unpacking the Dynamics of Customer Experience in AI-Infused Service Workflows

Cecilia Ying, Queen’s University, Markham, ON, Canada

As Generative AI transforms customer service, understanding the interplay between customers and agents is crucial. This study investigates the key drivers of negative customer experiences before and after AI integration, shedding light on the contrasting dynamics between the customers' interaction with the human-agent verses the AI-agent.

4 - One Versus Many: How Users Integrate Advice from Multiple Algorithms

Anna Taudien, University of Cologne, Cologne, Germany

Today, humans frequently receive algorithmic advice for prediction tasks in various fields such as healthcare, logistics, or finance. So far, existing research has primarily focused on collaboration settings where a user is advised by a single AI. However, the increasing presence of AI suggests that human-AI teams will likely involve multiple AIs in the near future. Yet, little is known on how humans will integrate advice from multiple algorithmic advisors into their judgment. In two between-subjects experiments ($n = 401$), we studied this advice-setting by having subjects perform surgery-duration predictions with varying numbers of algorithmic advisors. We find that users increase their weight on algorithmic advice when being advised by more than one algorithm. This not only occurs when the additional advice is beneficial (i.e., users can realize performance gains) but also when it is harmful (i.e., users impair their own performance). Hence, users do not seem to rationally include the additional algorithmic advice by weighing the different sources against each other. Instead, they appear to increase their reliance on algorithmic advice simply because more options are available. This behavior aligns with the bias of naïve diversification which describes the tendency of overly diversifying between different options. Our results contribute to the literature on AI-advised settings and have implications for organizations aiming to implement multiple algorithms as team members for humans.

5 - Learning about learning: Encouraging Algorithm Alignment through Progressive Deployment

Maya Balakrishnan, Harvard Business School, Boston, MA, United States, Bryce Mclaughlin

Across industries, managers’ decision-making processes evolve as their firms adopt new decision support systems (such as prediction algorithms). When a new algorithm is introduced to a user, the human’s responses to the algorithm are not static. The user’s initial interactions with the algorithm will drive how they learn about the algorithm and its performance and shape how they continue to use the algorithm in the future. At the same time, the algorithm needs to understand how users will respond to its deployment in order to effectively present its recommendations to achieve human-algorithm alignment. We propose a model by which a new algorithm is progressively deployed to heterogeneous users where users iteratively learn about the algorithm while the algorithm simultaneously learns about users and their response to the algorithm. We showcase our progressive algorithm deployment process in a series of simulated experiments and compare its performance against non-dynamic deployment processes, highlighting the importance of carefully managing not just what algorithm is deployed but how it is introduced.

Summit - 445

Sustainability in the Food Supply Chain

Invited Session

MSOM: Sustainable Operations

Chair: Sridhar Seshadri, University of Illinois, Champaign, IL, United States

Co-Chair: Sandeep Srinivas, University of Illinois at Urbana-Champaign, Champaign, IL, 61820

1 - Impact of Blockchain Technology on Food Safety

Sandeep Srinivas, University of Illinois at Urbana-Champaign, Urbana, IL, United States

Several regulatory bodies have underscored the significance of traceability in the food supply chain to safeguard consumer health. Numerous food and beverage companies have recently adopted blockchain technology to enhance supply chain traceability. This study empirically examines the effectiveness of blockchain traceability in improving food safety outcomes, specifically food recalls. We find that adopting blockchain traceability is associated with reducing recall duration for future recalls by firms. Additionally, we analyze the impact of blockchain traceability adoption on the number of recalls and recall volumes.

2 - Markdowns to Manage Food Waste and Its Impact on Retail Brand Image

Arzum Akkas, University of Massachusetts Amherst, Amherst, MA, United States

While marking down surplus food is an effective strategy to reduce food waste in retail, we discovered that many retailers, especially in the US, are reluctant to adopt this approach due to concerns about their brand image. Through both in-store and online experiments, we investigated whether markdowns have a negative impact on retailers' brand perception. Our findings revealed that they do not. Additionally, we found that the way markdowns are presented is important. Our online experiments also revealed geographical variations across the UK, US, Germany, France, and South Africa.

3 - Achieving Resilience with Redundancy in Food Bank Operations

Pelin Pekgun, Wake Forest University, Winston-Salem, NC, United States, Yingru Han, Luv Sharma, Olga Perdikaki

Food banks are non-profit organizations that collect food from sources such as retailers, manufacturers, and farmers, and distribute to the needy population. In this study, we investigate the role of redundancy-building strategies in affecting a food bank's level of resilience in food distribution in the case of a major disruption.

4 - Retail Food Donations and Operational Efficiency

John Lowrey, Northeastern University, Boston, MA, United States, Tim Richards, Anne Byrne

Retail unsaleables are often linked to an opportunity cost, since the resources used to produce leftover food could have otherwise been used more productively. Leftover food at retail has many potential uses, however, including donations to food banks. We examine the relationship between retail food donations and operational efficiency using a sample of 1,581 store-years across 14 major banners that donated to two major Feeding America member food banks from 2015-2021. We use stochastic frontier analysis and account for the endogeneity of key productive inputs using a control function framework. We find that food donations increased operational efficiency for stores located in more deprived areas. We link these results to potential differences in unsaleables management: stores in more deprived areas rely on donations to avoid cost, while stores in less deprived areas use donations to maximize quality (and profit). The cost-push vs. profit-pull difference may extend to other aspects of retail operations, beyond unsaleables management.

Summit - 446

Empirical Research on Operational Efficiency and Performance

Invited Session

MSOM:Technology, Innovation, and Entrepreneurship

Chair: So Yeon CHUN, INSEAD, France, Singapore

Co-Chair: Priscilla Rodriguez, INSEAD, Fontainebleau, France

1 - Algorithmic Decision Making in Healthcare: Role of Non-Clinical Call Handlers

Deepanshi Bhardwaj, UCL School of Management, London, United Kingdom, Bilal Gokpinar

Using data from NHS 111 and its Computer Decision system (Pathways), this paper aims to understand the extend to which service agents rely on and trust algorithms. To meet the growing demand of health services, the NHS uses a helpline number 111 to deal with urgent but non-life-threatening emergencies. These calls are handled by non-clinical staff using a Computer Decision Support System (NHS Pathways). In the precursor to NHS 111 (NHS Direct), the Decision Support System was designed to support, rather than replace, clinical decision-making. However, in case of NHS 111, there is an assumption (by NHS 111 service providers and by the technology developers) that clinical decision-making is primarily a function of the technology (provided that the call handler correctly identifies the appropriate computer algorithm). We identify possible errors that occur by over-reliance and under-reliance on Algorithmic Decision Support Tool and how the errors impact the Healthcare System.

2 - Performance Implications of Supply Chain Turnover

Kevin Mayo, Washington State University, Pullman, WA, United States, Christopher Chen, George Ball, Kurt Bretthauer

We examine the operational performance consequences of supply chain turnover. Analyzing a panel of buyer-supplier turnovers in the consumer goods industries, increasing turnover increases the consumer complaints, signaling a decrease in product quality, offsetting the decreased costs associated with turnover. We find that costs increase and quality remains the same when the turnover is due to the supplier exiting the market. We investigate the effects of distance and economic development on the supplier portfolio as mechanisms to explain the result.

3 - Going the extra mile? Workplace behaviors and performance outcomes.

Priscilla Rodriguez, INSEAD, Fontainebleau, France, So Yeon CHUN, Jurgen Mihm

In today's competitive corporate landscape, understanding the relationship between workplace behaviors and performance outcomes is crucial. We leverage privileged access to email and meeting data spanning over 12 thousand employees within a firm to understand the dynamics of employee behavior. Specifically, we focus on what we call "extra mile behaviors," characterized by employees' willingness to work extended hours and weekends. We analyze these behaviors in light of performance outcomes, focusing on differences in effects by employee characteristics and the potential for employee burnout.

4 - How Do Loyalty Programs Affect Multichannel Bookings? An Empirical Investigation

Shuaishuai Yang, UCL School of Management, London, United Kingdom, Antoine Feylessoufi, Ersin Korpeoglu, Lina Song

With the increased market power of online travel agencies (OTA), the hotel industry faces a new and important trade-off when working with OTAs: Potentially increasing sales at the expense of sizeable commission fees. In response, major hotel groups turn to loyalty programs, giving discounts to loyalty members for booking through their direct channels. In this paper, we investigate how successful loyalty discounts are in their goal to sway customers from OTAs to direct channels. Using a unique dataset obtained from a major hotel group, we empirically investigate how loyalty discounts affect customers' booking channel choices. We utilize a quasi-natural experiment based on an exogenous change of the loyalty discount in a subset of hotels in our dataset to construct a difference-in-difference model. We find that a larger loyalty discount raises bookings from the direct channel with loyalty membership,lowers bookings from the direct channel without loyalty membership, and has no significant effect on OTA bookings. This suggests that a substitution effect only occurs within the direct channel and, surprisingly, not cross-channels. Our results indicate that discount-based loyalty memberships do not have the intended effect of swaying customers from OTAs toward direct channels. Instead, directchannel customers utilize the loyalty program more, which may end up lowering hotel revenues. Therefore, our study suggests that the hotel industry should carefully assess the effectiveness and the design of their loyalty programs by factoring in their multichannel setting.

Use-inspired analytics and models tackling Human Trafficking

Invited Session

Public Sector OR

Chair: Felipe Aros-Vera, Ohio University, Athens, OH, United States

1 - Jennifer Ppt

2 - Optimum Allocation of Rehabilitation and Reintegration Services to Support Victims of Human Trafficking

Riad Al Hasan Abir, Ohio University, Athens, OH, United States, Felipe Aros-Vera

Human trafficking (HT) is a grave violation of human rights with far-reaching impacts, touching lives in every corner of the world. Despite the existence of government and non-profit rehabilitation services, HT-affected individuals often miss out due to improper resource allocation. To address this issue, we propose an optimization model that efficiently allocates resources to rehabilitate and reintegrate HT-affected individuals where those resources are most needed. Our strategy uses a Mixed Integer Linear Programming (MILP) model to maximize the net societal value (NSV) gained from offering support services while considering the three stages of the healing path for HT-affected people, including victim, survivor, and thriver. This model determines the optimal type, quantity, and location of services, while also integrating HT risk scores that account for the risk of HT in those areas. Our model's efficacy is demonstrated in a case study in Ohio, that allocates housing, detoxification, and food services across the state's eighty-eight counties and the three stages of the healing path of HT-affected individuals. Through Monte Carlo Simulation in the solution approach, uncertain demand is accounted for, leading to improved NSV under such conditions. Moreover, we illustrate the impact of an increased budget, showcasing the reach and allocation possibilities of extended services. Our work aims to support decision makers in efficiently allocating resources to rehabilitate and reintegrate HT-affected individuals effectively.

3 - Machine Learning Solutions in Identifying Potential Human Trafficking Recruitment During Humanitarian Disasters: Case Study of Ukraine

Amir Jamali, Worcester Polytechnic Institute, Worcester, MA, United States, Navid Ziaei, Renata Konrad

Humanitarian disasters increase vulnerabilities, as well as opportunities for exploitation, particularly of displaced people and refugees. Since the 2022 full-scale invasion of Ukraine, millions have been displaced, many unable to find licit employment and stable housing, putting them at risk of exploitation and human trafficking.

Online technologies such as home hosting sites and chat groups on social media are used to seek housing and employment, offering a lifeline to many but also facilitating exploitation.

We developed a machine learning model that uses natural language processing to analyze Telegram data, identifying potentially suspicious recruitment activities. This model classifies messages to pinpoint potential human trafficking communications. To handle multilingual data, we translated non-English messages into English, standardized non-text elements such as emojis, and tailored our methodology to accurately distinguish between suspicious and non-suspicious interactions.

To overcome data imbalance, we refined our labeling process and reduced the volume of non-suspicious data, enhancing the model's

performance and reliability. This approach allows us to identify vulnerabilities more effectively and supports specialists in directing prevention and rehabilitation efforts where they are most needed.
Our ongoing evaluation ensures the model's reliability in real-world applications. This automated tool saves considerable time in manual data screening, allowing NGOs and law enforcement to concentrate on intervention and support. The model not only contributes significantly to combating human trafficking in Ukraine but also offers a scalable solution adaptable to other regions, enhancing global anti-trafficking efforts.

4 - Modeling Human Trafficking Illicit Supply Networks

Felipe Aros-Vera, Ohio University, Athens, OH, United States, Stacie Petter, Gisela Bichler

With 50 million people affected around the world, human trafficking can (and should) be considered a humanitarian crisis. Illicit supply networks facilitate exploitation and threaten legitimate economic systems. Borrowing network science and criminology concepts, this presentation identifies key behavioral and networked characteristics that influence human trafficking within illicit supply networks.

5 - Improving Network Interdiction Models for Combating Labor Trafficking: Insights and Limitations

Priscila de Azevedo Drummond, Northeastern University, Boston, MA, United States, Arezoo Jafari, Kayse Lee Maass

Labor trafficking research faces considerable challenges due to data scarcity, surpassing even those encountered in sex trafficking studies. Although Network Interdiction Problem (NIP) models have been used to tackle crimes such as nuclear smuggling and drug trafficking, their application to labor trafficking is still in its early stages. Incomplete knowledge of the structural dynamics of trafficking operations and the extent of its prevalence influences this lack of publishing.
Our research focuses on the challenges of using NIP models to help reduce labor exploitation and proposes strategies to overcome them. However, assumptions and network structures chosen greatly impact the interpretative capabilities of these models. Through an interdisciplinary team, we build off expert knowledge to draw a more nuanced understanding of the models' relevance to the field. By exploring different models' assumptions, we found new opportunities for NIP model applications. Our findings have the potential to provide practical insights into the dynamics of labor trafficking and the effectiveness of anti-trafficking interventions.

6 - Does Deregulation Impact Firms' ESG Policy Compliance?

Jennifer Nowicki, Pennsylvania State University, University Park, PA, United States, Brian Lee, Kevin Linderman

The mining of conflict minerals is associated with regional violence, forced labor, and environmental devastation, which poses risks to firms' supply chains and therefore increases the potential for operational disruptions. As offshoring proliferated in the 2000s, these conflict regions have become increasingly entangled in firms' upstream supply chains, and the 2010 Dodd Frank Act requires firms to investigate and monitor their operations for the purpose of reducing risk. This legislation includes a conflict minerals provision to account for humanitarian risks imparted through conflict mining, which funds armed groups in the region. To comply with the legislation, firms must determine whether they are sourcing 3TG materials from a designated conflict region and report their findings to the SEC, however this provision was partially dismantled in 2017, providing an opportunity to observe firms' compliant behavior for both policy enactment and rollback. Through analyzing SEC documents via natural language processing, we explore how firms responded to the partial deregulation of the Dodd Frank Act's conflict minerals provision over a 10-year span, and evaluate firms' risk management systems through a due diligence framework. We find significant contingencies that impact firms' compliance behavior post-deregulation through a series of empirical analyses, and pair these findings with insights from industry practitioners. We then conclude with a discussion on a proposed compliance model for ESG-related policies, an increasingly relevant topic as ESG legislation propagates worldwide.

Advancements in Quantum Computing and Collaboration

Contributed Session

Chair: Jiaqi Leng, University of Maryland, College Park, MD, United States

1 - The co-evolution dynamics of multi-agent collaboration network in the emerging industry: A stochastic actor-oriented model in the field of quantum computing

Yingjie Ma, Zhejiang University, Hangzhou, China, People's Republic of, Xuansheng Wang, Qihan Yang, Zhiyang Liu, Lifan Chen

The realization of quantum supremacy highlights the potential of quantum computing to make a revolutionary difference. However, as an emerging industry, the quantum computing field has yet to establish a dominant design, leading to uncertain schemes of industrialization and commercialization. Drawing on the perspective of complex network and social embeddedness theory, this study explores the dynamics of collaborative innovation among key stakeholders and changes of research priorities in the field of quantum computing. Focusing on China and the United States as representative countries, this paper collects bibliographic data between 2001 and 2023 to construct inter-institutional collaboration networks. The present paper conducts two studies. In Study 1, we select a set of complex network measurements to characterize the evolution of topological structures of collaboration network in the quantum computing field. Additionally, we build dynamic topic models of the leading countries using BERTopic technique. Building upon the results in Study 1, Study 2 uses stochastic actor-oriented model (SAOM) to uncover the underlying mechanisms driving the co-evolution of collaboration network structures and innovation output of different agents, accounting for structural effects and agent attributes. The findings are: (1) Quantum computing is currently situated in a phase of fundamental research, marked by the dominance of academia, the increasing focus on market demands, and the consistent support from government; (2) Geographical, institutional, organizational, cognitive, and social proximity all influence the selection of collaborators, albeit variances at different stages; (3) The whole ecosystem remains unstable. Theoretical and managerial implications are discussed.

2 - Challenging the Quantum Supremacy Claim Using Learning-to-Anneal Algorithm

Xiao-Yang Liu, Columbia University, New York, NY, United States

Google's "quantum supremacy" announcement has received broad questions from academia and industry due to the debatable estimate of 10, 000 years' running time for the classical simulation task on the Summit supercomputer. Has "quantum supremacy" already come? Or will it come in one or two decades later? To avoid hasty advertisements of "quantum supremacy" by tech giants or quantum startups and eliminate the cost of dedicating a team to the classical simulation task, we take an open-source approach to maintain a trustable benchmark performance. We propose a novel learning-to-anneal algorithm, inspired by the simulated annealing algorithm and reinforcement learning algorithm, for the classical simulation of quantum circuits. We demonstrate its great potential by reporting an estimated simulation time of less than 4 days. Specifically, we formulate the classical simulation task as a tensor network contraction ordering problem, which is NP-hard by reducing to the problem of finding the ground state of Ising spin-glass model. We open-source our parallel gym environments and benchmarks and organize academic competitions to maintain the best performance of classical computers.

3 - The impact of collaboration networks on high-level scholars' innovation performance in the field of quantum information technology

baohuan zhou, University of Science and Technology of China, hefei, China, People's Republic of, Liang Liang

As a critical part of modern physics, quantum information technology is a field with thresholds, and analysis needs to be performed on high-level scholars. However, few studies have examined high-level scholars' innovation performance in the field from the perspective of collaboration networks. This article attempts to use methods such as bibliometrics, collaboration networks, and machine learning to fill these gaps. We constructed collaboration networks through two dimensions: scholars' egocentric networks and team networks. The effects were examined by considering two levels: innovation quantity and innovation quality. This study examines the connection between collaboration networks and high-level scholars' innovation performance. Meanwhile, 6,587 high-level scholars extracted from 202,614 papers between 2000 and 2020 in the field of quantum information technology were used for analysis. The results of the analysis show new features of the collaboration effect among many high-level scholars in the field of quantum information technology. In terms of scholars' egocentric networks, occupying an intermediary or structural hole location positively affects scholars' innovation performance. From the team networks perspective, there is an inverted U-shaped relationship between team size and high-level scholars' innovation quality. Team size should be approximately 50~60 scholars and be determined in ranges depending on goals.

4 - Using Neutral Atom-based Quantum Computing for Solving Hard Combinatorial Problems

Yassine NAGHMOUCHI, PASQAL, Massy, France, Yassine NAGHMOUCHI

Neutral atom technology has steadily demonstrated significant theoretical and experimental advancements, positioning itself as a front-runner platform for running quantum algorithms. One unique advantage of this technology lies in the ability to reconfigure the geometry of the qubit register, from shot to shot. This unique feature makes possible the native embedding of graph-structured problems at the hardware level, with profound consequences for the resolution of complex optimization tasks. By driving qubits, one can generate processed quantum states which retain graph complex properties. These states can then be leveraged to offer direct solutions to problems or as resources in hybrid quantum-classical schemes. In this talk, we'll present in detail how neutral atom-based quantum computing can tackle complex combinatorial tasks on solving graph-related optimization problems.

5 - Quantum-inspired algorithms for nonconvex quadratic programming

Jiaqi Leng, University of Maryland, College Park, MD, United States, Samuel Kushnir, Yuxiang Peng, Xiaodi Wu

Quantum algorithms have drawn increasing attention in the operations research community due to their promising performance for hard optimization problems. However, in the near future, the application of quantum algorithms to large-scale problems is still limited by the scalability of quantum computers. Recently, quantum-inspired classical algorithms have emerged as an active area of research because they preserve a quantum-like advantage while being fully executable on classical hardware. In this talk, we will introduce a family of quantum-inspired algorithms for quadratic programming, a fundamental task in nonlinear programming. Formulated as Hamiltonian dynamical systems inspired by quantum mechanics, these algorithms exhibit a desirable tunneling effect that is unseen in conventional first- and second-order methods. Local convergence results are established for these algorithms, and empirical results show that the output solutions are often globally optimal.

Causal Inference

Invited Session

Health Applications Society

Chair: Kyra Gan, Cornell Tech, Cornell University, New York, NY, United States

Co-Chair: Raaz Dwivedi, Cornell Tech, Cornell ORIE, New York City, NY, United States

1 - Decision-Centric Causal Structure Learning: An Algorithm of Data-Driven Covariate Adjustment

Chandler Squires, Carnegie Mellon University, Pittsburgh, PA, United States, Davin Choo, Arnab Bhattacharyya, David Sontag

When learning a causal model of a system, a key motivation is the use of that model for downstream decision-making. In this talk, I will take a decision-centric perspective on causal structure learning, focused on a simple setting that is amenable to careful statistical analysis. In particular, we study causal effect estimation via covariate adjustment, when the causal graph is unknown, all variables are discrete, and the non-descendants of treatment are given.

We propose an algorithm which searches for a data-dependent "approximate" adjustment set via conditional independence testing, and analyze the bias-variance tradeoff entailed by this procedure. We prove matching upper and lower bounds on omitted confounding bias in terms of small violations of conditional independence. Further, we provide a finite-sample bound on the complexity of correctly selecting an "approximate" adjustment set and of estimating the resulting adjustment functional, using results from the property testing literature.

We demonstrate our algorithm on synthetic and real-world data, outperforming methods which ignore structure learning or which perform structure learning separately from causal effect estimation. I conclude with some open questions at the intersection of structure learning and causal effect estimation.

2 - Doubly Adaptive Algorithms for Threshold Identification in Multi-Armed Bandits

Brian Cho, Cornell University, New York, NY, United States, Nathan Kallus, Kyra Gan

In this work, we investigate the thresholding bandit problem (TBP) and its variants. In TBP with W arms, a learner is given a threshold vector, with the goal of identifying the arms whose means are above their corresponding thresholds as quickly as possible. Prior works for TBP mostly focus sampling schemes for well-studied parametric bandit instances, with stopping rules based on loose concentration inequalities. In our work, we provide both adaptive sampling schemes and adaptive stopping rules for TBP and its variants based on anytime valid testing procedures, resulting in doubly adaptive algorithms for both parametric and nonparametric bandit instances. In particular, our anytime valid confidence testing procedure adapts to the optimal sequential test for the realized bandit instance, achieving instance-wise optimality when paired with the correct sampling scheme. We first illustrate the power of adaptive stopping rules in achieving instance-dependent lower bound in TBP. Next, we focus on a specific variant of TBP where the goal is to promptly identify one arm above its corresponding threshold. We introduce an adaptive sampling scheme and show that when paired with our proposed stopping rule, it achieves the instance-dependent asymptotic lower bound, showing the benefit of double adaptivity. To illustrate the practicality of our proposed method with finite samples, we conduct numerical experiments that highlight the superior performance of our methods compared to existing state-of-the-art algorithms.

3 - Learning Counterfactual Distributions via Kernel Nearest Neighbors

Kyuseong Choi, Cornell University, New York City, NY, United States, Jacob Feitelberg, Anish Agarwal, Raaz Dwivedi

Consider a setting with many units (individuals, cohorts, geographic locations) and multiple outcomes (treatment, time, items). For each unit and outcome, there is a multivariate distribution associated with it that we would like to learn. Challenge here is in real world settings, most cells are missing as is the case for recommender systems, or causal panel data settings with staggered adoption where a sub-collection of units get treated after a period of time. Further, for the cells that we do observe, we have only access to finite number of samples from underlying distribution rather than the distribution itself. We model this problem as a distributional matrix completion problem, and introduce kernel nearest neighbors algorithm to learn counterfactual distribution of missing cell. Under latent factor model on kernel mean embeddings of distributions and regularity conditions, kernel nearest neighbors enjoy rate guarantees when data is not missing at random and when positivity constraints are violated. We also illustrate how more than one samples per cell can effectively make nearest neighbors robust to heterogeneous data by constructing unbiased estimates of dissimilarity measures, which is otherwise not possible with only one sample.

4 - A New Perspective on Synthetic Controls

Yujin Jeong, Stanford University, Stanford, CA, United States, Dominik Rothenhäusler

In statistics and machine learning, we often want to quantify uncertainty and frame optimality with respect to sampling uncertainty. However, if we combine evidence from different data sets, sampling uncertainty might be lower order than the distribution shift between the data sets. This raises the question of how to optimally estimate in a data fusion setting. To address this issue, we model distributional shifts as a superposition of numerous random changes. We then develop tools for measuring the similarity between randomly perturbed distributions, estimating parameters and predicting outcomes for partially observed target distributions. Interestingly, these tools share a close connection to synthetic controls. Our framework provides a new language for distributional shifts and offers a fresh perspective on synthetic controls. Finally, we apply the framework to several real-world data sets and discuss diagnostics to evaluate the fit of the distributional uncertainty model.

5 - Counterfactually Comparing Abstaining Classifiers

Yo Joong Choe, University of Chicago, Chicago, IL, United States, Aditya Gangrade, Aaditya Ramdas

Abstaining classifiers have the option to abstain from making predictions on inputs that they are unsure about. These classifiers are becoming increasingly popular in high-stakes decision-making problems, as they can withhold uncertain predictions to improve their reliability and safety. When evaluating black-box abstaining classifier(s), however, we lack a principled approach that accounts for what the classifier would have predicted on its abstentions. These missing predictions matter when they can eventually be utilized, either directly or as a backup option in a failure mode. In this paper, we introduce a novel approach and perspective to the problem of evaluating and comparing abstaining classifiers by treating abstentions as missing data. Our evaluation approach is centered around defining the counterfactual score of an abstaining classifier, defined as the expected performance of the classifier had it not been allowed to abstain. We specify the conditions under which the counterfactual score is identifiable: if the abstentions are stochastic, and if the evaluation data is independent of the training data (ensuring that the predictions are missing at random), then the score is identifiable. Note that, if abstentions are deterministic, then the score is unidentifiable because the classifier can perform arbitrarily poorly on its abstentions. Leveraging tools from observational causal inference, we then develop nonparametric and doubly robust methods to efficiently estimate this quantity under identification. Our approach is examined in both simulated and real data experiments.

Clinical Decision Making for Chronic Disease

Invited Session

Health Applications Society

Chair: Hyojung Kang, University of Illinois at Urbana-Champaign, Champaign, IL, United States

Co-Chair: Jennifer Lobo, University of Virginia, Charlottesville, VA, United States

1 - Clustering Antidiabetic Medication Usage Patterns Using TIME Series Techniques

Peng Zhang, University of Illinois Urbana-Champaign, Urbana, IL, United States, Jennifer Lobo, Hyojung Kang, Min-Woong Sohn

Medication adherence in patients with type 2 diabetes has been suboptimal. Previous research has examined medication usage at the population level and revealed trends at specific treatment stages such as initiation and intensification. This study aims to develop a clustering model to categorize patients' medication usage patterns based on their longitudinal medication history. We focused on changes in medication usage patterns during the first year following metformin initiation. Dynamic time warping was employed to better evaluate the distances between different medication usage sequences. We examined the characteristics of clusters in terms of socioeconomic factors, as well as outcome measures, to understand the underlying disparities within diverse medication usage patterns and their impacts. The findings of this study will help identify high-risk patients for medication non-adherence and inform targeted patient management strategies.

2 - Machine Learning in the Emergency Department when the Class of Interest Adapts to System Congestion

M Gabriela Sava, Bowling Green State University, Bowling Green, OH, United States, Jerrold May, Ronald Pirrallo

Diabetes screening of Emergency Department/Urgent Care patients can proactively improve health outcomes, but it is uneconomic to screen all such patients. We present a data-driven analytical approach that could assist physicians with the diabetes screening decision. The approach is capable of selecting the most appropriate statistical model as resource availability and the patient's historical frequency of utilization change over time. Our findings show that when testing resources are more constrained, the predictive accuracy is greater for frequent users and decreases with patient visit frequency. Conversely, when testing resources are more available, the predictive accuracy decreases as patient visit frequency increases.

3 - Human-AI Interaction with Contextual Recourse Bandits

Ruijiang Gao, University of Texas at Austin, AUSTIN, TX, United States, Junyu Cao, Esmaeil Keyvanshokooh

This paper introduces a new paradigm called the \textit{Contextual Recourse Bandits} in online learning. The objective of this paradigm is to optimize outcomes by dynamically recommending actions and feature modifications. Drawing inspiration from practical healthcare scenarios where patients' features can be modified to qualify for more effective treatment options, we extend the traditional contextual bandit setup. Our contextual recourse bandit not only selects an action based on the current context but also suggests modifications to the context as recourses. These modified contexts have the potential to improve the outcome. To address this, we propose the Recourse Linear Upper Confidence Bound (RLinUCB), an innovative algorithm that jointly manages recourse and action recommendations, thereby balancing the exploration-exploitation trade-off. We provide theoretical guarantees demonstrating that RLinUCB achieves sublinear recourse regret under mild conditions. Furthermore, we offer a robust variant that accounts for noisy implementations of recourses. Empirical evaluations further validate the superior performance of RLinUCB compared to existing online contextual bandit algorithms. This work sheds light on a new direction in the contextual bandit literature that holds promise for advancing personalized healthcare among other fields.

4 - Comparison of Pancreatic Cyst Management Algorithms

Jennifer Lobo, University of Virginia, Charlottesville, VA, United States, Nasma Al-Humadi, Bryan Sauer, Ross Buerlein

Numerous guidelines exist for the management of pancreatic cysts that differ significantly in terms of their thresholds for imaging, surveillance, and surgery. We present a microsimulation model to compare outcomes for a cohort of patients managed with each guideline. Outcomes include mortality related to pancreatic cyst management, all-cause mortality, missed cancers, number of surgeries, number of imaging studies, cumulative cost, and quality-adjusted life years.

Transportation Network Design

Invited Session

The Practice Section of INFORMS

Chair: Chun Ye, Amazon.com, Seattle, WA, United States

1 - Ecommerce Delivery Speed Through a Queuing Equilibrium Perspective

Amitabh Sinha, Amazon, Seattle, WA, United States

Leveraging simple models and learnings from Amazon's Regionalization initiative, we will examine the role of capacity allocation in ensuring fast delivery speed. We will develop a simple queuing model and use it to illustrate the impact of capacity imbalances on delivery speed, and build on that to develop principles for network design.

2 - Data Driven Network Design

Chun Ye, Amazon.com, Seattle, WA, United States, Sukanya Kudva, Daniel Ulch

We study the problem of optimizing network connectivity by deciding which pair of facilities to connect via truck routes. We consider a model that jointly optimizes connectivity, truck scheduling, and package flow using a deterministic MILP. However, the model's simplifying assumptions about truck scheduling and package flow often don't match real-world operations, which leads to suboptimal connectivity decisions. To address this, we discuss a method to refine these assumptions and improve the model's decision.

3 - Translating Science into Business Impact

Shahbaaz Mubeen Mamadapur, Amazon, Seattle, WA, United States

Business leaders need robust tools to help them make the right decisions. However, many a times, science teams are unable to get business leaders/teams to adopt a suggested approach. In this talk, we discuss how we leverage scientific tools and build scalable OR products within Amazon. We will go through how basic software engineering architectures and principles enable us to decouple the problems and develop generalized products to solve network design problems across multiple geographies and programs. Finally, we walk through specific use cases where the generalized products empowered business leaders to make go/no-go investment decisions and evaluate alternate network design choices.

4 - The Fulfillment Regionalization Problem

Nidhima Grover, Georgia Institute of Technology, Atlanta, GA, United States, Xiaoyan Si, Alejandro Toriello

In today's retailing formats, retailers can choose which inventory location or Fulfillment Center (FC) to fulfill from, bringing opportunities of inventory pooling and providing a much broader product selection. The fulfillment decision, although complex, can bring financial gains when optimized for resources and operating costs. With the unprecedented growth of the retail industry, companies now have the opportunity to strategically divide their fulfillment networks into regional networks. Such a method, called regionalization, simplifies the fulfillment decision, is scalable, and has helped to increase fulfillment speed while lower cost at Amazon. The region definitions affect speed of delivery, cost to serve, and selection of products offered, which influences customer experience. We present a heuristic approach on how to partition the national network into regions that fulfill customer demand predominantly from a set of pre-assigned FCs, and benchmark solution quality against lower bound models.

Healthcare - Radiotherapy Cancer Treatment Applications

Invited Session

The Practice Section of INFORMS

Chair: Masoud Zarepisheh, Memorial Sloan Kettering, New York, NY, United States

1 - Portpy: Opensource Package for Planning and Optimization for Radiation Therapy in Python

Gourav Jhanwar, Memorial Sloan Kettering Cancer Center, New York, NY, United States, Mojtaba Tefagh, Qijie Huang, Vicki Trier Taasti, Seppo Tuomaala, Saad Nadeem, Masoud Zarepisheh

We have developed PortPy (Planning and Optimization for Radiation Therapy in Python), an innovative opensource software package designed to expedite the research and clinical translation of novel treatment planning techniques in radiation therapy. PortPy addresses the limitations of existing packages by offering several key features: 1) Interoperability with Commercial Systems, allowing for the objective evaluation of new techniques in comparison to the current clinical practices. 2) Inclusion of Benchmark Dataset, currently 50 lung patients, complete with clinical plans and all necessary data for treatment planning optimization. 3) Advanced Benchmark Algorithms, capable of identifying "global" optimal solutions, using computationally intensive mixed integer programming, for various non-convex optimization problems encountered in treatment planning

2 - Utilizing Data Compression and Dimensionality Reduction to Combat the Curse of Dimensionality in Radiotherapy Cancer Treatment

Masoud Zarepisheh, Memorial Sloan Kettering, New York, NY, United States

This study aims to leverage the dimensionality reduction tools to improve the speed and quality of radiotherapy planning. The dimensionality reduction has a rich history in statistics and has recently re-emerged as a powerful tool to deal with the problems arising in the fields of big-data and machine learning. The optimization problems arising in radiotherapy also suffer from the curse of dimensionality (e.g., many machine parameters, voxels). We show how matrix/tensor decomposition, in particular low-rank plus sparse decomposition, and wavelets can be employed to significantly improve the computational efficiency and plan quality. We also propose a novel algorithm for the low-rank plus sparse matrix decomposition and demonstrate the effectiveness of the new algorithm on radiotherapy problems as well as background separation problems in computer vision.

3 - Optimal Dose Scheduling with Variable Fraction Sizes and Intervals via Sequential Mixed-Integer Convex Programming

Anqi Fu, Memorial Sloan Kettering, New York, NY, United States, Joseph O. Deasy, Zeno Gouw, Jeho Jeong

Hypofractionated radiotherapy has proven successful in local disease control, particularly for early-stage lung cancer. However, treatment is typically delivered via a constant dose schedule, which ignores the impact of cellular resource limits and reoxygenation on tumor response. We developed a method for constructing dose schedules with variable fraction sizes and intervals that exploits the difference in radiosensitivity between proliferating and resource-starved (hypoxic) cells. Our method formulates the dose scheduling problem as a finite-horizon optimal control problem, where the states are the proliferating/hypoxic cell counts and the controls are the dose fractions. The state transition dynamics are defined by a tumor response model of cellular resource competition and radiosensitivity. Since these dynamics are nonlinear, we designed an iterative optimization algorithm that solves a sequence of convex surrogates to arrive at an approximate solution to the problem. The resulting schedules consist of an initial large "primer shot" dose, followed by a 1-2 week break, and concluding with a short sequence of small doses. The primer shot targets the proliferating cells at the beginning since they are most radiosensitive; during the treatment break, these cells undergo post-mitotic cell death, freeing up resources so that hypoxic cells can reoxygenate. The newly reoxygenated cells have higher radiosensitivity and consequently require only 1-4 small doses to achieve the clinically-desired tumor control probability. Simulations on an early-stage lung cancer cohort showed that the primer shot schedule produces an average 6% reduction in local failures and 58% reduction in normal tissue BED3 compared to a constant dose schedule.

4 - Robust Optimization in Volumetric Modulated Arc Therapy for Prostate Cancer

Stoyan Hristov, University of Waterloo, Waterloo, ON, Canada, Houra Mahmoudzadeh, Ernest Osei, Johnson Darko

Volumetric modulated arc therapy (VMAT) is a type of radiation therapy in which a beam of radiation moves across an arc around the patient, continuously delivering radiation to a cancerous target. The goal of treatment plan optimization is to maximize radiation to cancerous cells and minimize damage to nearby healthy organs while ensuring that a set of mechanical constraints are met. VMAT is often used for prostate cancer treatment, which suffers from geometric uncertainty due to setup errors and changes in the patient's anatomy between treatments.

As such, we propose a VMAT model that uses robust optimization to optimize a minmax function and ensure that clinical criteria are met under uncertainty. The proposed model generates deliverable VMAT plans that are robust to a worst-case scenario. This talk will further motivate the research question, describe our methodology, and share preliminary results.

5 - Optimal Fractionation Plans in Temporally Feathered Radiation Therapy

Aysenur Karagoz, Rice University, Houston, TX, United States, Soheil Hemmati, Andrew Schaefer

Intensity-modulated radiation therapy (IMRT) remains the standard-of-care radiation therapy technique for most head-and-neck cancer (HNC) patients. Despite the relatively high survival rate of HNC (65-75%), the survivors often suffer from post-treatment long-lasting side effects, which negatively affect their quality of life. In an IMRT-based treatment plan, the daily doses delivered to the tumor and organs-at-risk (OARs) remain fixed based on the premise that the one-day inter-fraction suffices for each OAR's recovery. However, a novel treatment planning approach, referred to as temporally feathered radiation therapy (TFRT), proposes variable daily dose delivery to the OARs, aiming at increasing the recovery time of OARs at the cost of receiving higher doses once a week. While limited implementations of TFRT have shown promising results both in the simulations and in the clinic, they do not distinguish between the inherent radiobiological differences between the OARs for HNC patients, thus prescribing longer, yet uniform recovery time for all OARs. By recognizing variable radiosensitivity profiles across multiple OARs for HNC radiation therapy, we develop a mixed-integer nonlinear program (MINLP) that computes specific recovery time for each OAR to minimize the toxicity burden to the patients. Our proposed MINLP leverages the linear-quadratic model, which predicts each OAR's survival from radiation-induced damages. Our model is further flexible in addressing specific prioritization of OARs based on the clinician's preferences. The result of our model indicates a lower overall toxicity burden when OARs with higher radiosensitivity have longer recovery times under the TFRT framework.

Summit - Signature Room

Retail Price Optimization

Invited Session

The Practice Section of INFORMS

Chair: Elizabeth Cubbage, Petco, Fort Collins, CO, 80528, United States

1 - Using Consumer Price Perception to drive Optimal Pricing Strategy

Elizabeth Cubbage, Western Union, Fort Collins, CO, United States

Consumers often form price perceptions based on a limited set of goods rather than their entire basket. This research identifies key consumer price perception driving good types and the implications for pricing strategy.

2 - Revolutionizing Retail Pricing using GenAI

Sanjeewa Naranpanawe, OATL, Morrisville, NC, United States

In today's highly competitive retail landscape, pricing strategies can make or break a business. Traditional methods of pricing are often too rigid, slow, and fail to account for the dynamic nature of consumer demand and market trends.

Large Language Models such as GPT-4, are powerful tools for analyzing consumer sentiment, extracting insights from data, and generating dynamic pricing strategies. By processing textual data from social media, customer reviews, and market reports, LLMs can identify emerging trends and shifts in consumer preferences, providing retailers with a competitive edge.

Additionally, LLMs can facilitate personalized pricing by analyzing individual customer behavior and preferences, enabling retailers to tailor prices and promotions to maximize customer satisfaction and loyalty. These models can also be integrated into customer service chatbots and virtual assistants, providing real-time price recommendations and support.

3 - Lift Estimates and Schedule Optimization for Trade Promotion Planning

Maarten Oosten, Vistex, Inc., Cary, NC, United States

Trade promotions consist of the multi-level promotional activities of a manufacturer. The manufacturer sells their products via independent retailers to the consumers. They offer these retailers promotional programs to support their sales efforts. The manufacturers must incentivize the retailers to execute the promotions. After all, if a promotion is not attractive to the retailer, there won't be a promotion. Therefore, the manufacturer should model the behavior of the consumers as well as the behavior of the retailers. In this presentation, we discuss the challenges this poses in both the estimation of the promotion effects and the optimization of the promotion schedule.

4 - The effects of constraints on markdown price optimization

Nicholas Wegman, Zebra Technologies , Oak Park, IL, United States

For fashion and seasonal items, taking the right markdowns are essential to driving incremental revenue and minimizing excess inventory. It is well established that price optimization software can improve upon this business process by suggesting better markdown prices. However, the effectiveness of an optimized price is heavily influenced by the optimization constraints set by the user. In this talk we will discuss the importance of and methods for understanding how much optimality is lost by applying different constraints

Generative AI and Creative Problem Solving

Invited Session

Information Systems

Chair: Leonard Boussioux, UW Foster, Harvard, Seattle, WA, 98122, United States

1 - Placeholder

Alex Burnap, Yale University, New Haven, CT, United States

2 - Generative AI and Creative Problem Solving

Miaomiao Zhang, Harvard Business School, Boston, MA, United States

The rapid advances in generative artificial intelligence (AI) open up attractive opportunities for creative problem-solving through human-guided AI partnerships. To explore this potential, we initiated a crowdsourcing challenge focused on sustainable, circular economy business ideas and assessed the novelty, value, and creativity of solutions created by both the human crowd and the collaborative efforts of one human and AI. The challenge attracted 125 global solvers from various industries and the human-prompted AI solutions were generated using strategic prompt engineering. We recruited 300 evaluators to judge a randomized selection of 13 out of 234 solutions, totaling 3,900 evaluator–solution pairs. Our findings demonstrate that the solutions generated through human-AI collaboration matched the creativity of those from the human solvers. Whereas the human-AI solutions provided more value, the human-only solutions were more innovative—both on average and for highly novel outcomes. Our study explores the potential for incorporating “AI-in-the-loop” into creative problem-solving, offering a scalable and cost-efficient method for enhancing the early phases of innovation. Our research paves the way for future exploration of how AI can be integrated into creative processes to foster more effective innovation.

3 - Generative AI and Evaluations of Early-Stage Innovations

Leonard Boussioux, University of Washington, Foster School of Business, Seattle, WA, United States, Charles Ayoubi, Ian Chen, Justin Ho, Jacqueline Lane, Camila Lin, Pei-Hsin Wang, Miaomiao Zhang

The rise of generative AI has transformed creative problem-solving, necessitating reevaluating idea evaluation processes to effectively assess and select from the resulting abundance of solutions. This study investigates how human-AI collaboration can enhance early-stage evaluations of innovative solutions, examining the interplay between objective criteria, which are quantifiable and measurable, and subjective criteria, which are based on personal opinion and intuition. Partnering with MIT Solve, a marketplace for social impact innovation, we conducted a field experiment involving 72 experts and 156 community screeners evaluating 48 real-world solutions for the 2024 Global Health Equity Challenge for a total of 3,002 screener-solution pairs. We utilized GPT-4 to provide recommendations and explanations for screening decisions. Our experiment compared a human-only control condition against two AI-assisted treatments: a black box AI providing recommendations without explanations and an explainable AI offering both recommendations and rationales for its decisions. Our findings reveal that screeners strategically use AI insights, validating AI’s recommendations when they agree and scrutinizing AI recommendations when they disagree. Screeners assisted by AI were roughly 9 percentage points more likely to fail a solution than the control group, primarily influenced by AI’s more stringent failure recommendations. Data from interviews and mouse tracking reveal that AI explanations for subjective criteria led screeners to doubt their own human judgment and possibly over-rely on AI’s explanations. This research suggests a possible framework for human-AI collaboration in creative evaluation, where AI complements human judgment on objective criteria while humans retain primary responsibility for subjective assessments supported by AI insights.

4 - LLM for Demand Forecasting

Dingli Ma, University of Washington, Seattle, WA, United States

Prior literature suggests that human forecasters typically overreact to forecast errors in relatively stable environments but underreact to errors in relatively unstable environments. We train an LLM for demand forecasting and investigate whether the trained LLM can overcome systematic judgment biases.

Shaping Perceptions and Identities in Social Media

Invited Session

Social Media Analytics

Chair: Reihane Boghrati, Arizona State University, Tempe, AZ, United States

1 - Intersectional stereotypes in everyday language: Evidence across race, gender, and social class

Tessa Charlesworth, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Kshitish Ghate, Aylin Caliskan, Mahzarin Banaji

Social group-based identities intersect. The meaning of “woman” is modulated by adding social class as in “rich woman” or “poor woman”. How does such intersectionality operate at-scale in everyday language of the internet and social media? Which intersections dominate (are most frequent)? What qualities (positivity, competence, warmth) are ascribed to each intersection? Here, we make it possible to address such questions by developing a new stepwise procedure, *Flexible Intersectional Stereotype Extraction* (*FISE*), applied to word embeddings (*GloVe*; *BERT*) trained on billions of words of English Internet text revealing insights into intersectional stereotypes. First, applying FISE to occupation stereotypes across intersections of gender, race, and class showed alignment with ground-truth data on occupation demographics, providing initial validation. Second, applying FISE to trait adjectives showed strong androcentrism (*Men*) and ethnocentrism (*White*) in dominating everyday English language (e.g., *White+Men* are associated with 59% of traits; *Black+Women* with 5%). Associated traits also revealed intersectional differences: advantaged intersectional groups, especially intersections involving *Rich,* had more common, positive, warm, competent, and dominant trait associates. Together, the empirical insights from *FISE* illustrate its utility for transparently and efficiently quantifying intersectional stereotypes in existing large text corpora, with potential to expand intersectionality research across unprecedented time and place. This project further sets up the infrastructure necessary to pursue new research on the emergent properties of intersectional identities.

2 - Does Authenticity Matter in the Age of AI Music?

Yifei Wang, University of New Hampshire, Durham, NH, United States, Yunfei Wang, Jui Ramaprasad

<p break-words""="">This study examines how the release of the generative AI model GPT-4 in March 2023 impacted music consumption patterns, focusing on the role of perceived authenticity as a key driver. The advent of AI music composition has sparked debates around copyright, originality, and AI's potential threat to artistic integrity. We argue that GPT-4's release motivated consumers to increasingly seek out music perceived as more authentic through raw production and earnest self-expression. Analyzing a novel dataset from Spotify's influential "New Music Friday" playlist, we investigate demand shifts at both the genre and artist levels using difference-in-differences models with propensity score matching. We find GPT-4's release increased weekly streaming by 5.19% for the more authentic Electronic genre compared to Pop. At the artist level, original artists (credited as composers/producers) experienced a 3.94% additional streaming increase over non-original artists after GPT-4's launch. We further explore the interaction of originality and proficiency (measured by major label association) as composite authenticity indicators. Our findings provide early evidence on how consumers assess music authenticity in the AI era, with authentic genres and original, lower-proficiency artists receiving amplified demand following GPT-4's release. This offers insights for industry stakeholders navigating the changing landscape as generative AI shapes evolving authenticity perceptions.

3 - A Multi-Modal Assessment of User Engagement in How-to Videos on YouTube

Maryam Rahmani Moghaddam, University of Delaware, Newark, DE, United States, Xiao Liu, Anjana Susarla, Rema Padman

YouTube how-to videos have proven to be an effective means of patient education. However, producing engaging and high-quality how-to videos is not easy. This study examined YouTube videos related to diabetes-related topics to provide practical insights into how to create high-quality videos that facilitate patient understanding and engagement. Drawing on the literature on cognitive load theory and the cognitive theory of multimedia learning we propose a set of visual and verbal features that can affect the cognitive load of learners while learning new skills or knowledge. In particular, we construct features that capture visual complexity in terms of color and objects displayed. For narratives, we focus on the amount and flow of information conveyed. In addition, eleven acoustic features such as pitch and intensity are used to quantify vocal modality. Our study indicates that vocal features have a greater impact on user engagement as measured by the number of views and likes. Findings from the study can benefit health consumers, patient educators, and health organizations.

4 - Impact of Weight Stigmatization on Avatar Selection in the Metaverse

Sungeun Han, Arizona State University, Tempe, AZ, United States, Reihane Boghrati

While weight discrimination manifests in diverse dimensions including workplaces, and schools, people have been facing weight bias online with the rise of social media. The increased anonymity makes it easy to post memes, and comments that would perpetuate body shaming and weight prejudice from behind the screen. It is not limited to social media, in more real-time interactions virtual realm including metaverse, distorted weight-related attitudes and beliefs can be more problematic. In the metaverse where users have complete autonomy to create their own digital avatars, body shaming, and weight stigma can influence the way users represent themselves in the digital realm. Grounded in self-discrepancy theory, previous studies found that people tend to reconstruct their digital identities to fulfill their ideal selves. Through the lens of self-discrepancy theory, this study delves into the influence of weight stigmatization on consumer behavior in avatar selection within the metaverse. Furthermore, we investigate how weight-stigmatized users cope with stigmatization through compensatory consumption, such as purchasing luxury items in the virtual realm as a way of coping with stigmatization. Additionally, we seek to understand how avatar selection behavior may vary depending on different social contexts, where users interact with friends or strangers. As the metaverse expands, there is a rising concern over the lack of diverse avatar options, with a noticeable predominance of thin avatars. Through our study, we aim to promote a more inclusive digital environment emphasizing the importance of avatar diversity by offering an in-depth understanding of how digital identity intertwines with weight stigma.

5 - Unveiling the Heart of a Social Movement: Analyzing the Drivers of User Engagement on Social Media for #Blacklivesmatter

Adrija Majumdar, Indian Institute of Management Ahmedabad, Ahmedabad, India, Chellapilla Deep Prakash, Rajiv Gopinath

Social movements fundamentally reshape societal norms through their advocacy for justice, equality, and human rights. Prior research has explored social media's role in user engagement, emphasizing cultural influences on content creation and its subsequent effects on communication, information spread, and societal change. This study builds on existing literature by specifically focusing on how different content types—sensationalist, justice-oriented, objective, or action-oriented—influence user engagement within the context of social movements. Employing the Uses and Gratifications Theory, which posits that individuals selectively use media to satisfy distinct needs such as information, entertainment, and social integration, our analysis centers on social movement-related posts tagged with #BlackLivesMatter during the heightened periods of activism in August 2017 and May 2020. Our methodological framework includes exploratory data analysis, the creation of a specialized dictionary, feature engineering, and regression analysis to identify key engagement drivers. The results indicate that sensationalist content markedly increases user engagement, with additional factors like follower count, tweet length, and multimedia presence also significantly contributing. This research not only deepens insights into the dynamics of media consumption during pivotal social movements but also offers guidelines for crafting effective digital content. Highlighting the importance of analyzing engagement drivers, this study shows that increased engagement fosters greater awareness and more efficient information dissemination, thereby amplifying the influence of social movements. Our findings contribute to the ongoing discourse on the pivotal role of social media in supporting social movements.

To Accredit or Not To Accredit: That is the Question

Panel Session

Education Outreach

Co-Chair: Ken Murphy, Merage School - UC Irvine, 4293 Pereira Drive, Irvine, CA, 92697, United States

1 - Moderator Panelist

Ken Murphy, Merage School of Business, UC Irvine, Irvine, CA, United States

2 - Panelist

Laura Albert, University of Wisconsin-Madison, Madison, WI, United States

This panel will discuss academic program accreditation for business analytics/data science, ABET, and standards alignment with the Certified Analytics Professional (CAP). Panelists will share their experience with advocating for the value of accreditation, building appropriate administrative support, and executing certification acquisition and maintenance activities. Opportunities for INFORMS to grow with respect to academic program accreditation will also be considered.

3 - Panelist

Alper Atamturk, UC Berkeley, Berkeley, CA, United States

4 - Panelist

Bill Griffin, INFORMS, Catonsville, MD, United States

5 - Panelist

Naser Nikandish, Johns Hopkins Carey Business School, Washington, DC, United States

Machine Learning in Decision-Making: Strategies and Interpretability

Invited Session

Artificial Intelligence

Chair: Wangsheng Zhu, Hong Kong University of Science and Technology , Hong Kong, N/A, Hong Kong

1 - Care for the Mind Amid Chronic Diseases: An Interpretable AI Approach Using IoT

Jiaheng Xie, University of Delaware, Newark, DE, United States

Health sensing for chronic disease management creates immense benefits for social welfare. Existing health sensing studies primarily focus on the prediction of physical chronic diseases. Depression, a widespread complication of chronic diseases, is however understudied. We draw on the medical literature to support depression prediction using motion sensor data. To connect human expertise in the decision-making, safeguard trust for this high-stake prediction, and ensure algorithm transparency, we develop an interpretable deep learning model: Temporal Prototype Network (TempPNet). TempPNet is built upon the emergent prototype learning models. To accommodate the temporal characteristic of sensor data and the progressive property of depression, TempPNet differs from existing prototype learning models in its capability of capturing the temporal progression of depression. Extensive empirical analyses using real-world motion sensor data show that TempPNet outperforms state-of-the-art benchmarks in depression prediction. Moreover, TempPNet interprets its predictions by visualizing the temporal progression of depression and its corresponding symptoms detected from sensor data. We further conduct a user study to demonstrate its superiority over the benchmarks in interpretability. This study offers an algorithmic solution for impactful social good - collaborative care of chronic diseases and depression in health sensing. Methodologically, it contributes to extant literature with a novel interpretable deep learning model for depression prediction from sensor data. Patients, doctors, and caregivers can deploy our model on mobile devices to monitor patients' depression risks in real-time. Our model's interpretability also allows human experts to participate in the decision-making by reviewing the interpretation of prediction outcomes and making informed interventions.

2 - Interpretable Feature Selection for Predictive Analytics: A Bayesian Perspective

Wei Feng, University of Maryland, College Park, MD, United States, Kunpeng Zhang

Feature selection aims to select a pertinent subset of features, thereby shrinking dimensionality of dataset to enhance machine learning model efficacy. It has seen widespread success across various domains. A major hurdle, however, is the nature of ‘black-box’ in most prior studies: the importance and interplay of chosen features are often nebulous, posing significant risks in critical areas like finance and healthcare. To tackle this, several well-known model-agnostic interpretative frameworks like SHAPLEY and LIME have been suggested to elucidate the relationships between features and outcomes. This is not satisfactory, due to the fact that two other key research gaps remain unfilled: automatically determining the optimal size of selected features and unraveling the inter-feature relationships. This paper introduces a novel Bayesian-based feature selection framework that integrates structural learning with the Markov blanket theory in predictive models. This method not only selects informative features but also shows the pathways leading to outcomes, therefore boosting interpretability. The proposed framework was empirically validated against established benchmark models using both real and simulated data. Results showed that (i) using the selected features from our method achieves better performance than several state-of-the-art baselines, and even comparable to using full features. (ii) the statistical 'causal' relations among features are also generated, which is very useful in practice. (iii) On simulated data, the framework accurately identified predefined relationships among variables, achieving over 80% accuracy with few false positives.

3 - Investigating ideational shifts across technological generations in the telecom industry

Tzu-Wen Lin, The University of Texas at Arlington, Arlington, TX, United States, Sridhar Nerur, Jayarajan Samuel, Ruochen Liao

The transition from 3G to 5G technologies in the telecommunications industry has sparked a debate on whether it represents a fundamental paradigm shift or merely an incremental technological advance. This research delves into this transformation, utilizing patent data and advanced techniques from network science and text analytics to elucidate the nature of ideational changes in the innovative landscape of telecommunications.

Employing methods such as machine learning prediction and topic modeling, the study evaluates lexical differences across telecommunication generations, thereby offering insights into the industry's level of disruption. Furthermore, this research investigates the pivotal role of knowledge as a source and the nature of knowledge interchange between firms, tracing the innovative evolution of top-performing companies from the 3G era to the present time. By unraveling the intellectual structure of innovations in the telecommunications domain, the research provides invaluable perspectives on the dynamics of technological change and the significance of knowledge exchange in shaping the industry. Through this comprehensive endeavor, the study aims to deepen our understanding of the cross-generational shifts occurring within the telecommunications industry, shedding light on the nature and implications of the transition from 3G to 5G.

4 - Navigating the Unknown: Optimizing Advertising Strategies in the Face of Ad Auction Uncertainty

Wangsheng Zhu, Hong Kong University of Science and Technology , Hong Kong, Hong Kong, Shaojie Tang, Vijay Mookerjee

Online advertising has emerged as a popular method for firms to promote their products. Unlike the offline context, where advertising slots are predetermined, most online advertising slots are sold through real-time auctions. The outcome of these auctions is influenced by various factors, including the number of competing advertisers. Consequently, firms launching advertising campaigns face uncertainty regarding the number of slots they will secure.

While previous studies have examined optimal advertising strategies assuming accurate knowledge of ad exposure, the impact of slot acquisition uncertainty during ad auctions remains unexplored. Building upon existing literature, we propose a diffusion equation that explicitly models the randomness associated with slot acquisition in ad auctions. By validating our model using a real-world dataset, we demonstrate that firms currently operate sub-optimally by overlooking slot acquisition randomness when launching ad campaigns. Furthermore, we illustrate how our model can be utilized to derive optimal advertising strategies that account for slot acquisition uncertainty, leading to improved profitability for advertisers. Additionally, apart from maximizing expected sales, firms may also aim to maintain low sales variance for effective inventory management. Our model accommodates this consideration, allowing firms to derive optimal advertising strategies that strike a balance between mean and variance of sales.

5 - From Rankings to Decisions: Deep Learning-Based Aggregation Methods

Shuzhang Cai, The University of Texas at Dallas, Richardson, TX, United States, Shaojie Tang

Many decision-making processes, such as participatory budgeting or candidate recruitment, involve collecting and aggregating participants' voting results. Obtaining accurate utility scores from voters can be challenging; instead, they often use rankings to indicate their preferences. Different methods of aggregating these rankings can lead to varying outcomes. In this paper, we aim to develop a deep learning-based system to effectively aggregate these rankings and produce a consensus decision. Our approach addresses the practical difficulties of utility estimation while enhancing the reliability of the final decision.

Personalized and Fair AI: Advances in Federated Learning and LLMs

Contributed Session

Chair: Chong Oh, Eastern Michigan University, Ypsilanti, MI, United States

1 - Tailoring Large Language Model to Satisfy Fine-Grained User Needs: A Novel Deep Learning Method

Shujie Liu, Zhejiang University, Hangzhou, China, People's Republic of, Gang Chen, Xiangwei Kong

The powerful language comprehension and content generation capabilities of large language models (LLMs) imply great potential for commercial applications. However, when applied to domain-specific conversation scenarios, they often yield vague and generic responses, failing to fulfill personalized user needs. In this paper, we frame personalized user needs as need coverage and need specificity based on information processing theory, and strive to tailor LLM to satisfy fine-grained user needs. To achieve this, we propose a novel deep learning method named MSA-PAT, which synergizes two components, i.e., MSA for inferring multi-granularity user needs based on conversation text and PAT for tailoring the LLM's generated responses toward fine-grained user needs satisfaction through prompt adaptation and self-supervised LLM fine-tuning. Empirical evaluation in two question-answer case studies demonstrates the satisfactory response generation capability of MSA-PAT toward fine-grained user needs. Ablation, sensitivity analyses and case studies provide insights into how MSA-PAT generates responses to satisfy fine-grained user needs.

2 - Personalized Federated Learning via Learning Shared Representation: Statistically Optimal Rates

Xiaochun Niu, Northwestern University, Evanston, IL, United States, Lili Su, Jiaming Xu, Pengkun Yang

Personalized federated learning enables clients and a central server to collaboratively learn a shared model while allowing individual clients to fine-tune and adapt the model to their specific needs privately. Current literature primarily focuses on algorithmic advancements and assumes that the local data volume far exceeds the model dimension, leaving the optimal sample complexity unresolved.

In this paper, we determine the optimal sample complexity when clients share a common low-dimensional linear representation. We characterize statistically optimal rates for both unsupervised and supervised learning settings. Specifically, we establish information-theoretic lower bounds on estimation errors and design a federated method-of-moments estimator with local averaging to achieve these bounds. Our results demonstrate that the optimal error rates match those in centralized learning with a moderate number of agents and local dataset sizes. However, a statistical penalty arises due to distributed computing when there are many agents with insufficiently large or heterogeneous local datasets.

3 - Enhancing Group Fairness in Federated Learning Through Personalization

Yifan Yang, The Ohio State University, Columbus, OH, United States, Ali Payani, Parinaz Naghizadeh

Instead of producing a single global model for all participating clients, personalized Federated Learning (FL) algorithms aim to collaboratively train customized models for each client, enhancing their local accuracy. For example, clients could be clustered into different groups in which their models are similar, or clients could tune the global model locally to achieve better local accuracy. In this paper, we investigate the impact of personalization techniques in the FL paradigm on local (group) fairness of the learned models, and show that personalization techniques can also lead to improved fairness. We establish this effect through numerical experiments comparing two types of personalized FL algorithms against the baseline FedAvg algorithm and a baseline fair FL algorithm, elaborate on the reasons behind improved fairness using personalized FL methods, and provide analytical support under certain conditions. Based on these findings, we further propose a fairness-aware clustered FL algorithm and analyze the convergence rate of this algorithm in a convex and smooth setting. Our experiment results demonstrate that our proposed algorithm has improved fairness compared to classical clustered FL, which could lead to an improved fairness-accuracy tradeoff.

4 - Strategic Retraining of LLMs: Variance, Value, and Competitive Dynamics

Ehsan Valavi, Massachusetts Institute of Technology, Cambridge, MA, United States, Joel Hestness, Marco Iansiti, Newsha Ardalani, Feng Zhu, Karim Lakhani

This paper investigates the strategic and operational implications of retraining large language models (LLMs) in diverse business contexts. By analyzing user-generated content from Reddit, we identify significant variations in data perishability and retraining frequencies across different domains. Our findings indicate that rapidly evolving topics, such as politics and world news, require more frequent updates, while stable areas like relationship advice and history benefit from less frequent retraining. We introduce the concept of "data effectiveness" to measure predictive power over time, emphasizing the necessity for continuous access to fresh data in dynamic environments.

Our study highlights the complementary role of human expertise in providing up-to-date data, especially in fast-changing contexts where LLM performance relies heavily on current information. In more stable domains, historical data retains its value, allowing for the use of more sophisticated models. We discuss the implications of data perishability for AI strategies, advocating for flexible data management systems that support frequent model updates to maintain relevance.

This research contributes to the literature on AI economics, data valuation, and strategic management, offering insights into optimizing LLM retraining to enhance business competitiveness and productivity. It underscores the importance of adapting LLM deployment strategies to the pace of change within specific domains, ultimately shaping the future of data-driven decision-making and competitive advantage.

5 - Data sharing through federated learning in supply chain: a game theoretical analysis

Yonghua Ji, University of Alberta, Edmonton, AB, Canada, Huimin Ma

Federated learning has been used to improve operations and protect privacy in various industries. This study focuses on the use of federated learning in the supply chain context. By utilizing local models provided by its clients, an equipment manufacturer could use federated learning technology to train a global model and improve the operations of its equipment in its clients' factories. Through a game theoretical model, we study how the equipment manufacturer can motivate the clients to participate in its federated learning platform. Furthermore, we study the effect of federated learning on the clients' and the manufacturer's profits and social welfare.

6 - Enhancing Mental Health Support Through AI: A Study on High-Contingency Chatbots and Social Support Theory

Chong Oh, University of Utah, Salt Lake City, UT, United States, Matthew Pecsok, Carina Pals, Rishi Ramesh

This study aims to explore the efficacy of AI chatbots in providing social support to college students facing academic stress, framed within the context of Social Support Theory. We will conduct an experiment comparing high-contingency and low-contingency chatbots with human support providers. Participants will be randomly assigned to interact with one of these support types and subsequently complete surveys evaluating perceived support, cognitive reappraisal, emotional validation, and emotional distress. High-contingency chatbots, leveraging advanced natural language processing (NLP) to deliver context-aware and personalized responses, will be contrasted with low-contingency chatbots that offer generic, scripted replies. Our hypothesis is that high-contingency chatbots will be perceived as more competent and warmer, thus more effective in reducing emotional distress through enhanced cognitive and emotional engagement. This research seeks to contribute to Information Systems (IS) by demonstrating how AI-driven, adaptive communication technologies can be designed to emulate human-like support and improve mental health outcomes. By integrating Social Support Theory with cutting-edge AI, this study aims to provide actionable insights for developing intelligent, empathetic chatbot systems in the mental health domain.

Mitigating Bias and Enhancing AI Collaboration

Contributed Session

Chair: Aida Khosh Raftar Nouri, Memorial university, 200 Crestview Church Road, Apartment #1405, Warner Robins, GA, 31088, United States

1 - To Automate or Not? How Open Collaboration Communities Decide on Bot Adoption

Lei Nico Zheng, University of Massachusetts Boston, Boston, MA, United States, Zihan Chen, Feng Mai

AI tools are widely used in open collaboration communities nowadays, yet factors influencing their adoption are not well understood. This study investigates the factors influencing bot adoption on English Wikipedia. Leveraging the advanced capabilities of Large Language Models (LLMs) on NLP tasks, we systematically extract human-computer interaction (HCI) factors from 2,155 Wikipedia Bot Request for Approval pages. We identify ten themes emerged form community discussion concern three main aspects: Technological Factors, User Interaction and Experience, and Platform Governance. We further assess the comparative importance of each theme in the community's bot adoption decisions. Our findings reveal that Technological Factors play the most significant role, followed by User Interaction and Experience and Platform Governance Standards. This study contributes quantitative evidence to understanding bot adoption in open collaboration communities and proposes a novel, generalizable LLM-based approach for extracting and summarizing themes from large text corpora.

2 - Advancing Decision Support with Generative AI and Human-AI Collaborations in Multi-Agent Systems

Seonho Woo, Purdue University, West Lafayette, IN, United States, Young-Jun Son, Seung ho woo

This study proposes a novel decision-making framework leveraging generative AI and multi-agent systems to enhance human-AI collaborations. This framework employs synthetic data to train AI agents and circumvents privacy concerns while magnifying the robustness of experiments in simulated experiments. Incorporating a generative AI enables the system to create a variety of scenarios dynamically, mimicking complex contexts in real-world decision-making and allowing for extensive testing and refinement of AI behaviors in controlled, safe settings.

This research focuses on developing decision support in the multi-agent system in which AI agents generate and evaluate potential decisions so that they collaboratively work with human inputs to optimize outcomes. This setting improves decision accuracy and enhances the AI-system adaptability simultaneously to unpredictability and human strategies. Various complexity levels in decision-making tasks are included in experiment designs and are utilized to assess the effectiveness of human-AI collaboration and cooperation of AI agents and human operators in real time.

Our goal is to signify the effect of a generative AI-enhanced multi-agent framework for decision support that can enhance the decision-making process for the system where human plays a significant role and AI agents are advantageous concurrently. This approach enables human traits to be benefited from AI capabilities in human-run operating systems, and this leads to more efficient and informed decision-making processes in various applications with higher performance.

3 - Mitigating Omitted Variable Bias through the Design of Data Collection Interfaces

Aida Nouri, Memorial university , Warner Robins, GA, United States

This study explores the potential impact of omitted variable bias in machine learning (ML), which may arise from traditional class-based data collection methods. Such methods, by limiting data collection to predefined categories, might inadvertently overlook important features of entities, leading to possible biases. We investigate this phenomenon by contrasting class-based data collection with a flexible instance-based data collection approach, hypothesizing that the latter can capture a broader spectrum of attributes and more accurately reflect real-world phenomena.

Using a comparative experimental design, participants will interact with objects in videos, categorizing and describing them through both class-based and instance-based methodologies. The class-based method may confine data to predefined attributes, potentially limiting the richness and variability of the collected data. In contrast, the instance-based method is expected to allow detailed, unrestricted descriptions, leading to a richer dataset that better captures the nuances and complexities of real-world entities.

Our study aims to employ sensitivity analysis to investigate the extent of omitted variable bias under each data collection methodology, examining the robustness of model estimations with variable modifications. By doing so, we seek to understand how different data collection practices influence the quality and reliability of ML models. This research contributes to the broader understanding of data collection practices in ML and other data-driven fields, advocating for more inclusive and dynamic methods for data collection. By adopting more flexible and comprehensive data collection approaches, we aim to improve the overall reliability and validity of ML models and other analytical tools.

TC69

Regency - 607

SpORts III

Invited Session

spORts

Co-Chair: Keith Willoughby, University of Saskatchewan, Saskatoon, SK, Canada

1 - Analysis of the Push Phase of the 2022 Olympic Bobsled Competition

Aaron Hoskins, California State University, Fresno, Fresno, CA, United States

The push phase is critical in bobsled competition because extra speed at the top of the mountain results in a significant reduction in the time required to finish the run. This work analyzes the dynamics of all teams from the 2022 Olympic Bobsled competition to determine characteristics that separated the teams from each other.

2 - Post COVID, Higher-Rated Women's Teams Won More Often and Higher-Rated Men's Teams Won Less Often, Likely Due to Women's Greater Team Cohesiveness

Raymond Stefani, California State University, Long Beach, Lake Forest, CA, United States

A pre-COVID 2007-2019 data base was gathered to study all team sports that had international recognition, had an official rating system published by the governing federation and had a world championship (WC). The higher-rated women's teams won only 0.25% more than the men's teams. Post-COVID, 11 WCs were contested during 2021and 2022, and early in 2023, in the five sports using the same rating system as pre-COVID and contested by both men and women. In all five sports, the percentage of games won by the higher-rated men's team was lower post-COVID: curling (-6.1%), rugby 7s (-12.9%), T20 Cricket (-8.9%), basketball (-12.6%), and rugby union (-2.0%). However, in all five sports, the women's higher-rated teams had higher percentages post-COVID: curling (+7.3%), rugby 7s (+6.2%), T20 cricket (+7.0%), basketball (+5.0%) and rugby union (+0.4%). A review of the coaching literature suggests that during the COVID-era restrictions, adverse conditions triggered an increase in women's social cohesiveness, which drove increased team cohesiveness, creating increased cooperative learning and execution of tactical skills, whereas men emerged from those adverse training conditions with less team cohesiveness and predictability.

3 - The Canadian men's curling championship: Simulating the path to the podium

Keith Willoughby, University of Saskatchewan, Saskatoon, SK, Canada, Kent Kostuk

For nearly a century, Canadian curlers have annually competed in a national championship known as the "Brier". Regulations dictate that the championship entrants include at least one team from each Canadian province and territory. Starting in 2014, curling officials gave an automatic "Brier" bye to the previous year's winner. The championship field was recently increased to an 18-team event with the addition of "wild card" entrants. We develop an analytical model to determine the probability that any team captures the national championship trophy. In addition, we investigate the fairness of automatic byes for the previous year's champion.

4 - Predicting March Madness Upsets with Gradient Boosting Models

Gabriel Forthofer, USAFA, Colorado Springs, CO, United States

The NCAA Men's Basketball Tournament, known as March Madness, is a high-stakes, single-elimination college basketball event that captivates audiences with its unpredictable upsets and "Cinderella stories." We apply the machine learning technique of Gradient Boosting Model (GBM) to predict these upsets. Utilizing a dataset spanning from 2002 to 2022, we compile team statistics and match outcomes to train our model. We evaluate model performance using accuracy and feature importance metrics, revealing insights into the dynamics of March Madness upsets. Preliminary results indicate a promising capability of the GBM in predicting upsets with significant accuracy, offering a novel approach to understanding and forecasting outcomes in one of America's most thrilling sports events. This study not only contributes to the field of sports analytics but also enhances the understanding of applying advanced predictive models in team strategy development.

Stochastic Resources Bidding in Flexibility Markets

Invited Session

ENRE: Electricity

Chair: Jalal Kazempour, Technical University of Denmark, Kgs. Lyngby, Denmark

Co-Chair: Lesia Mitridati, Technical University of Denmark, Kgs Lyngby, Denmark

1 - A Risk-Aware Approach to Optimizing Frequency Reserve Dimensioning

Alessandro Zocca, Vrije Universiteit Amsterdam, Amsterdam, Netherlands

One of the main responsibilities of Transmission System Operators (TSOs) that operate an electric grid, is to maintain a certain frequency (e.g., 50 Hz in Europe). To be able to do so, TSOs have created several products that are called "frequency supporting ancillary services". The Frequency Containment Reserve (FCR) is one of these ancillary service products and to some TSOs it is unclear how to dimension it. In our work, we study the risk effect of changing the often fixed FCR obligation to a dynamic approach. We take the Nordic synchronous area in Europe as case study and use a diffusion model to capture its frequency development and introduce a controlled mean reversal parameter to assess changes in FCR obligations, in particular for the FCR-D ancillary service product. We establish closed form expressions for exceedance probabilities and use real life (frequency) data to study the risk effects numerically.

2 - Reach and Hold Flexibility Characterization for Aggregations of Thermostatically Controlled Loads

Mazen Elsaadany, University of Vermont, Burlington, VT, United States

Thermostatically controlled loads (TCLs) have the potential to be flexible and responsive loads to be used in demand response (DR) schemes. With increasing renewable penetration, DR is playing an increasingly important role in enhancing power grid reliability. The aggregate demand of a population of TCL's can be modulated by changing their temperature thermostat setpoint. When and/or what proportion of the population sees the thermostat setpoint change determines the change in aggregate demand. However, since the TCL population is finite, not all changes in aggregate demand can be maintained for arbitrarily long periods of time. The dynamic behavior of a TCL fleet is modeled and *used to characterize the set possible changes in aggregate demand that can be reached and the corresponding time for which the demand change can be held, for a given change in thermostat setpoint. This set is referred to (in this work) as the 'reach and hold set' of a TCL fleet. Furthermore, the effect of the size of the thermostat setpoint change on the reach and hold set is analyzed. The characterized set is then validated through simulation using both the population TCL models and individual TCL micro-models.*

3 - Chance-constrained bidding strategy for a flexibility aggregator of stochastic distributed units in Nordic FCR-D markets

Torine Reed Herstad, Technical University of Denmark, Kgs. Lyngby, Denmark, Jalal Kazempour, Bert Zwart, Lesia Mitridati

The provision of ancillary services can offer an additional source of revenues for flexible loads, including those with stochastic power consumption baselines, such as Electric Vehicles (EVs). In order to harness this flexibility, the Danish transmission system operator, Energinet, sets a minimum reliability requirement of 90% for stochastic flexibility providers participating in the Nordic primary ancillary service (FCR-D) market. In this context, we study the optimal bidding strategy of an aggregation of EVs in the FCR-D market. The minimum reliability conditions are modelled using joint chance-constraints, and novel exact solution methods using extreme value theory are proposed. The dependence between the upward and downward flexibility at different hours is investigated using copulas and it is discussed to which extent the assumption of independence leads to over-bidding. The performance of the proposed solution methods is analyzed empirically and compared to a Sample Average Approximate (SAA) solution method on a realistic case study consisting of aggregated charging boxes in Danish households.

4 - Market Operations & Battery Storage Conundrums

Ben Hobbs, Johns Hopkins University, Baltimore, MD, United States

The rapid penetration of storage batteries in bulk power markets pose challenges to the traditional thermal plant paradigms of optimal dispatch and market power mitigation. Present market designs are not up to these challenges for several reasons, including stochasticity, abbreviated time horizons, the need to estimate opportunity costs, presence of price caps, and degradation costs. These challenges and possible responses to them by market designers are reviewed.

1 - Healthy Bio-Core: An Instance Selection Framework for Enhancing Biomedical Temporal Data Classification

Abhidnya Patharkar, ARIZONA STATE UNIVERSITY, Tempe, AZ, United States

Numerous existing machine learning methods engage in instance selection, specifically instance filtering, to eliminate outliers or samples that are on the edge. We present a new technique for conducting instance selection on multivariate time series data. We explore the implementation of this technique in identifying a representative subset of the healthy class in three biomedical temporal data sets. This selected subset is referred to as a 'Healthy Bio-Core' (HBC). Our approach involves the utilization of dynamic time warping and Gaussian distribution to create the HBC. Unlike conventional methods that often rely on clustering algorithms such as the k-nearest neighbors algorithm for instance filtering, which necessitates specifying the parameter k, our algorithm eliminates the need for parameter specification by leveraging the classification accuracy of the ROCKET (Random Convolutional Kernel Transform) algorithm. The results demonstrate enhanced performance when using HBC compared to all healthy data. To further validate the performance, we employ three classifiers: HIVE-COTE (Hierarchical Vote Collective of Transformation-based Ensembles), MUSE (Multi- variate Unsupervised Symbols and Derivatives) and DTW-NN (Dynamic Time Warping with Nearest Neighbor), assessing accuracy and F-1 score of classification for HBC versus abnormal data, and healthy versus abnormal data.

2 - A Multi-Scale Self-Corrected Masked Autoencoder with Brain Tumor Applications

Hairong Wang, Georgia Institute of Technology, Atlanta, GA, United States

Glioblastoma (GBM) is one of the most aggressive and lethal human cancers. Intra-tumoral genetic heterogeneity poses a significant challenge for treatment. Biopsy is invasive, which motivates the development of non-invasive, MRI-based machine learning (ML) models to quantify intra-tumoral genetic heterogeneity for each patient. This capability holds great promise for enabling better therapeutic selection to improve patient outcome.

3 - Blobcut: a Contrastive Learning Method to Support Small Blob Detection in Medical Imaging

Teng Li, Arizona State University, Tempe, AZ, United States

Medical imaging-based biomarkers derived from small objects (e.g., cell nuclei) play a crucial role in medical applications. However, detecting and segmenting small objects (a.k.a. blobs) remains a challenging task. In this research, we propose a novel 3D small blob detector called BlobCUT. BlobCUT is an unpaired image-to-image (I2I) translation model that falls under the Contrastive Unpaired Translation paradigm. It employs a blob synthesis module to generate synthetic 3D blobs with corresponding masks. This is incorporated into the iterative model training as the ground truth. The I2I translation process is designed with two constraints: (1) a convexity consistency constraint that relies on Hessian analysis to preserve the geometric properties and (2) an intensity distribution consistency constraint based on Kullback-Leibler divergence to preserve the intensity distribution of blobs. BlobCUT learns the inherent noise distribution from the target noisy blob images and performs image translation from the noisy domain to the clean domain, effectively functioning as a denoising process to support blob identification. To validate the performance of BlobCUT, we evaluate it on a 3D simulated dataset of blobs and a 3D MRI dataset of mouse kidneys. We conduct a comparative analysis involving six state-of-the-art methods. Our findings reveal that BlobCUT exhibits superior performance and training efficiency, utilizing only 56.6% of the training time required by the state-of-the-art BlobDetGAN. This underscores the effectiveness of BlobCUT in accurately segmenting small blobs while achieving notable gains in training efficiency.

4 - Interpretable Deep Learning Framework for Understanding Molecular Changes In Human Brains with Alzheimer&Rsquo;S Disease

Maitry Ronakbhai Trivedi, Arizona State University, Tempe, AZ, United States

The potential of Artificial Intelligence (AI) in investigating the genetic irregularities spanning various brain regions affected by Alzheimer's disease (AD) is yet to be fully explored. Specifically, there exists a significant gap in identifying common and specific transcriptomic signatures that characterize AD-related cellular and molecular processes. This undertaking shows potential in illuminating new insights into the biology of the disease, aiding in the identification of biomarkers, and facilitating the discovery of targets. Therefore, we propose an extensive deep-learning approach that consists of Multi-Layer Perceptron (MLP) to classify the AD vs controls using the bulk-RNA sequence data from three different brain regions in the Religious Orders Study/Memory and Aging Project (ROSMAP) from the RNAseq Harmonization Study of the AMP-AD consortium. Utilizing predicted embeddings of the MLP, we model the distribution of expression profiles as a progressive disease trajectory across distinct brain regions. To enhance the interpretability of MLP models, we employ SHapley Additive exPlanations (SHAP) values and identify the most significantly AD-implicated genes, which serve as key nodes for subsequent gene co-expression network analysis. Our models exhibit robust performance in classification and prediction, validated across two external datasets: the Mayo RNA-seq (MAYO) cohort and the Mount Sinai Brain Bank (MSBB) cohort of AMP-AD. This research emphasizes the transformative capacity of AI in unraveling the complex molecular mechanisms of AD, surpassing conventional approaches to reveal novel insights into the disease's pathogenesis.

1 - Deep Learning for Overheating Prediction in 3D Printing: A CNN-LSTM Approach Informed by Geo-Sequential Feature Engineering

Samar Saleh, Rutgers, The State University of New Jersey, Piscataway, NJ, United States, Weihong Guo

In additive manufacturing or 3D printing, precise control of thermal processes is pivotal for ensuring product quality. Overheating, a prevalent challenge, can significantly compromise the structural integrity of 3D-printed parts. This study introduces a novel predictive modeling approach for overheating in 3D printing that circumvents the direct quantification of thermal behaviors. Through advanced feature engineering, we have incorporated geo-sequential data and scanning patterns into the dataset, enriching it with structured spatial and sequential context. We propose a hybrid Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM) model architecture that synergistically exploits spatial patterns and sequential data inherent in 3D printing processes. The CNN component is responsible for extracting spatial features, while the LSTM layers model the sequential dependencies to predict the Consolidated Overheating Ratio (COR). This model has demonstrated superior predictive performance compared to traditional methods, as evidenced by rigorous validation on a comprehensive dataset. While overheating has only been understood qualitatively in the past, the proposed approach can effectively predict overheating quantitatively without requiring explicit thermal data. This simplifies the predictive process and enables real-time corrective measures in the printing parameters. This study not only advances overheating prediction methodologies but also contributes as an expandable framework for enhancing quality control in additive manufacturing.

2 - Transfer Learning Model for Industrial Prognostics

Kyoung Min Kim, North Carolina State University, Raleigh, NC, United States

In this talk, we investigate transfer learning within the context of high-dimensional location-scale regression models. Our goal is to improve the model's accuracy on target data by using relevant information from appropriate source data. We have developed two algorithms: The first is a transfer learning algorithm for the location-scale regression model, which assumes that all sources are transferable. The second is a Transferable Source Detection algorithm that determines which sources among the available data can be transferred. Additionally, we will present experiments to demonstrate the effectiveness of these two algorithms.

3 - Heterogeneity-aware Federated Learning for Collaborative Fatigue Life Prediction in Additive Manufacturing

Anyi Li, Auburn University, Auburn, AL, United States, Jia Liu

Accurately predicting the fatigue life of additive manufactured (AM) parts from inspection and testing data is crucial for their adoption in critical applications like aerospace. However, inspection and testing specimens are too limited to build an accurate predictive model for individual manufacturers. Federated learning (FL) is a promising technique enabling privacy-preserving, collaborative learning with a network of distributed AM manufacturers. However, the data among manufacturers are often heterogenous (i.e., non-IID) due to distinct machines, process conditions, or build volume, paralyzing the FL deployment for quality control in distributed AM. To alleviate this issue, we propose a heterogeneity-aware FL model for fatigue life prediction among AM manufacturers. The proposed model mainly tackles the non-IID data problem across distributed AM manufacturers' machines by integrating data heterogeneity in the FL training model. During training, it will regulate and balance the model weights between global FL and local individual AM manufacturers' models to mitigate the non-IID constraints while maintaining their model performance for fatigue life prediction. This model can benefit manufacturers with different capabilities in accurate fatigue life prediction.

4 - A Physics-Informed SPC Approach to Machine Health Monitoring for Two-Photon Lithography

Sixian Jia, University of Michigan - Ann Arbor, Ann Arbor, MI, United States, Zhiqiao Dong, Chenhui Shao

Two-photon lithography (TPL) is an advanced additive manufacturing technique to produce three-dimensional (3D) micro- and nano-scale structures. Like any complex manufacturing processes, machine health conditions of TPL systems can significantly affect the performance and quality of the fabricated structures. As such, effective and efficient monitoring of the machine health status and timely maintenance interventions are crucial to ensure consistent and high-quality production. Presently, maintenance practice for TPL machines is heavily experience-based and not informed by the real-time machine conditions. These maintenance strategies can lead to inefficiencies and non-timely interventions, thus compromising product quality. To date, there exists very limited research on machine health monitoring for TPL. Integrating new physics informed structure dimension models with classical statistical process control (SPC) philosophy and methods, this paper develops three approaches for accurate and timely monitoring of TPL machine health conditions. A large-scale experiment consisting of six TPL process parameter combinations and six structure dimensions was repeated under two machine health conditions to provide the data for assessing the effectiveness of the proposed approaches. It is shown that all three approaches are highly effective with an accuracy of up to 100 %. Importantly, the approaches are shown to have excellent robustness and generalizability. To the best of our knowledge, this research is among the first to investigate the maintenance issue in TPL.

Transforming Education Through Data Analytics

Invited Session

Data Mining

Chair: Alessandro Hill, University of Bologna, Bologna, Italy

Co-Chair: Puneet Agarwal, California Polytechnic State University, San Luis Obispo, CA, United States

1 - Course Content Mining for Academic Program Selection

Puneet Agarwal, California Polytechnic State University, San Luis Obispo, CA, United States

Prospective students have to make the challenging decision of selecting a university program that will lay the foundations of their academic and professional career. For the decision maker and support services, it is often difficult and time-consuming to match personal interests with suitable programs and their complex and vast catalogue data behind. We present the first data mining-based information system that allows students to efficiently obtain recommendations that stem from both the collective program content and their personal interests. We use machine learning to analyze all available course descriptions and extract interest topics, represented by significative keywords that characterize learning content. Underpinned by the student's individual indication of interests, a ranked shortlist of most relevant programs is computed through a statistical backtracking method. In a case study at a post-secondary institution with over 80 undergraduate study programs and more than 5,000 courses, the system is capable of providing immediate and effective decision support. A qualitative study involving 65 students demonstrates that the presented interest topics are meaningful and allow for positive effects such as serendipity, personalization and fairness. Over 98% indicated that the recommendations matched their interests and about 94% agreed to using this tool in the future.

2 - Admission Process Optimization: A Two-Stage Decision Framework

Meiling Wu, University of California, Irvine, Irvine, CA, United States

The competition to attract top candidates is intense for universities, as applicants often apply to multiple schools. While scholarship offers can serve as a powerful tool to influence applicant decisions, the utility derived from financial aid incentives is heterogeneous among candidates and constrained by budgetary limitations. Furthermore, the admission process has multiple rounds, wherein the number of offers extended in each round can impact subsequent admission decisions. To address these complexities, this paper proposes a two-stage decision framework designed to optimize admission outcomes, enabling institutions to attain targeted enrollment figures while curating a class portfolio that aligns with their desired characteristics. The first stage involves predicting the enrollment probabilities of applicants based on their individual characteristics, academic performance, extracurricular activities, demographic information, and personal statements to generate probabilistic predictions of applicant enrollment. The second stage leverages these predictions by applying optimization to maximize expected utility for the institution. By assigning weights to different attributes and preferences, the algorithm optimizes the selection process while ensuring alignment with target enrollment numbers and class composition objectives.

3 - Effectively Expanding Student's In-Class Social Networks using Analytics

Alessandro Hill, California Polytechnic State University-San Luis Obispo, San Luis Obispo, CA, United States

A strong and diverse peer network is important for students' educational, personal, and professional success. We present novel methods for augmenting students' ties during class based on social network analysis. First, we explain how optimized project group assignment can create new connections. Secondly, we show how to achieve the latter using optimized seating arrangements in arbitrary classroom layouts. We solve the underlying hard combinatorial problems, variants of the set partitioning problem and the assignment problem, to optimality as integer programs using mathematical optimization. We describe the practical implementation of our techniques and account for both student and instructor needs. In case studies including more than 300 industrial engineering students, we analyze the potential and quantify the actual impact. Finally, we report student and instructor feedback which supports the usefulness of our approaches.

4 - Gamifying Analytics Education: Using Cryptocurrencies to Enhance Learning Outcomes in Business Undergraduates

Nicolas Nunez, Centrum PUCP, Lima, Peru

Addressing low analytics skills among business undergraduates, our study used cryptocurrencies in a game-like setting to boost learning outcomes in a Data Analytics course. Our experiment involved 41 students who were each given USD 10 in cryptos. They were tasked to apply their knowledge in statistics and predictive modeling to manage their crypto assets effectively. Our aim was to prevent loss in their portfolio's value while applying the concepts. Results were promising: 85% of the students completed all their tasks, 95% reported a high level of enjoyment, and interestingly, all participants profited, coinciding with a rise in prices. Our findings show that gamified, real-world scenarios can significantly enhance educational outcomes.

Equity in the Energy Transition

Flash Session

ENRE: Energy-Climate

Chair: Erin Baker, Univ of Massachusetts-Amherst, Amherst, MA, United States

1 - The cost of inclusive electrification in sub-Saharan Africa

Ayse Selin Kocaman, Bilkent University, Ankara, Turkey, Beste Akbas, Alper Yilmaz, Ozlem Karsu, Philipp Trotter, Destenie Nock

The United Nations' Sustainable Development Goal 7 aims to ensure access to affordable, reliable, sustainable, and modern energy for all. Currently, there are 770 million people without access to electricity, with 75% residing in Sub-Saharan Africa. Decision-makers in countries with incomplete electrification systems face the challenge of increasing access rates while reducing system inequality. This paper proposes a framework that integrates data-driven analysis and optimization to estimate the cost of planning with an emphasis on fairness, departing from the traditional approach of cost-minimization planning. The study achieves this by incrementally increasing electricity access and solving a cost-minimizing model with and without Gini constraints, considering both on-grid and off-grid options in the electrification process. The Gini constraint aims to mitigate disparities in electrification rates across counties within underdeveloped countries. Consequently, we identify the additional cost of incorporating regional inclusivity into electrification planning. This analysis is exemplified for select countries in Sub-Saharan Africa.

2 - Evaluating equity outcomes of low-carbon energy transitions

Ranjit Deshmukh, University of California Santa Barbara, Santa Barbara, CA, United States, Sage Kime, Measrainsey Meng, Haozhe Yang, Wen-Tien Wang

Low-carbon energy transitions, while crucial for mitigating climate change, can cause energy justice and equity impacts on historically disadvantaged communities. Evaluating equity outcomes of past and potential policies, regulations, and programs enabling a low-carbon energy transition is crucial for the transition to be just. In this talk, we will present a framework that identifies and classifies energy justice and equity metrics into dimensions of health, access and livelihood to evaluate the effects of decarbonization initiatives. We will then present results from two studies that evaluate the potential equity outcomes of future low-carbon energy transitions. The first study focuses on the health and employment impacts of the phaseout of crude oil extraction and refining in the United States and the distribution of those impacts across race, income, and historically disadvantaged status. The second study focuses on the distribution of health and employment impacts of China's low-carbon transition in the electricity sector across its provinces.

3 - Carbon Capture and Co-pollutants in a Networked Power System

Paola Furlanetto, UMass Amherst, Boston, MA, United States, Erin Baker

Carbon Capture (CC) is an interesting technology for decarbonization of many sectors, including the power system. There are, however, major uncertainties about its impacts on the emission patterns of the power grid. This happens because while CO2 emissions affect the entire planet, co-pollutants (other emissions from fossil fuel generators, like NOx and SOx) are harmful for those directly exposed. CC guarantees removal of CO2 but the data is uncertain when it comes to co-pollutants and this has particular consequences for people of color and low-income who usually live nearby the power plants.

In this work we evaluate how CC affects the stock and distribution of airborne pollutants, considering technological uncertainties and policy design. We employ a Power Flow model of a three-node, mixed-source network in which fossil fuel power plants may invest in CC via retrofit. The policies include a system-wide cap on CO2, a carbon price, and a conjuncture on US rules (45Q Tax Credit, EPA Rule 111 and Good Neighbor). We report the extent of CC adoption, the energy source mix, the airborne emissions (CO2 and co-pollutants) and the monetized damages to human health. Our work shows that co-pollutant dynamics must be considered in the first steps of CC policy design, otherwise there can be stark consequences for public health.

4 - Robust Portfolio Analysis of Electricity Investments Under Net-Zero Uncertainties

Erin Baker, Univ of Massachusetts-Amherst, Amherst, MA, United States

Policy-makers and planners are looking to make robust energy system investments under deep uncertainty and conflicting objectives. This analysis presents a robust portfolio approach to address a range of uncertainties and multiple objectives and applies it to inform U.S. electric sector decisions under deep decarbonization. Results point to many plausible pathways to reaching economy-wide net-zero emissions: six of nine portfolios considered are non-dominated. Wind and solar generation play large roles in non-dominated portfolios, while dominated portfolios tend to retain fossil fuel capacity, which can increase costs and emissions. This analysis highlights the importance of considering fuel price uncertainty and, in particular, the possibility of high natural gas prices, which can lead to high co-pollution in otherwise low-polluting portfolios. Results illustrate trade-offs between emissions and costs; as well as between CO2 and co-pollutants, which is largely due to the use of carbon removal.

5 - Climate Change Impacts on Low-Income Household Energy Costs in the US

Camilo Toruño, University of Michigan, Ann Arbor, MI, United States

Mitigating climate change impacts on low-income communities is particularly important due to historic injustices, unique vulnerabilities, and low culpability for the climate crisis [1]. This report studies climate change impacts on low-income household energy burdens in the United States. Energy burdens challenge nearly a quarter of US households, and recent scholarship shows some climate scenarios have a 10-20% increases in energy burdens in the summers of Phoenix, and New York City [2, 3, 4, 5]. This research seeks to expand the field with modeling and analysis of climate change impacts on energy burdens of low-income households across 15 U.S. cities covering all contiguous U.S. climate zones. Our results show that climate change when considered across annual seasons causes monthly energy burdens to shift from winter to summer, with an overall slight decrease in energy burdens. The energy burdens in summer increase and winter decrease under RCP 8.5 by 6.6% and 9.1% respectively, corresponding to absolute energy burdens change of about 1-1.5%pt (percentage points). For low-income households that have high energy burdens (> 10%pt), any increase can be financially unmanageable, and any decrease could provide important relief. Shifting when low-income households pay for energy can be very challenging, and with warmer summers we can expect higher demand for AC adoption, yet low-income households may struggle to afford purchasing and running air conditioning. These compounding concerns highlight the need for managing low-income household's thermal comfort, carbon emissions, as well as energy burdens.

6 - Energy and economic security analysis across multiple scales in the Grid Operations, Decarbonization, Energy and Environmental Equity Platform (GODEEEP)

Kendall Mongird, Pacific Northwest National Laboratory, College Park, MD, United States, Stephanie Waldhoff

Ambitious climate policy requires major energy sector transitions, impacting energy producers, suppliers, and consumers. Pacific Northwest National Laboratory's Grid Operations, Decarbonization, Energy and Environmental Equity Platform (GODEEEP) moves beyond *how* to achieve these major transitions to explore their impacts on energy and economic well-being at multiple scales, within a consistent modeling framework.

Understanding all of these impacts requires a framework that can simultaneously explore the effects of technological change induced by GHG mitigation policies and changing socioeconomic conditions. Many of the policy-relevant metrics cross multiple spatial, temporal, and demographic scales. The GODEEEP research has focused on modeling metrics of residential energy security by income-deciles at the state level and jobs and income impacts at the county level in Washington State.

Residential energy security results show uneven impacts across income groups and states under the net zero scenarios, relative to the reference, with the largest changes in energy burden for middle-income consumer groups. For instance, the inequality in energy burden varies both within and across states and increases in the net zero scenario, with increasing shares of income spent on energy under the Net-Zero transition scenario. However, there are also positive impacts of this transition, such as an increase in the number of power sector jobs, as states transition to clean power sources.

Sustainable Transportation Operations

Invited Session

ENRE: Environment and Sustainability

Chair: Isil Koyuncu, The University of Texas at San Antonio, San Antonio, TX, United States

1 - Strategic Deployment of Electric Vehicle Charging Infrastructure in South Korea: Location and Capacity Planning

Jin ah Yang, LHRI, Seoul, Korea, Republic of, Na Rea Cho

While electric vehicles (EVs) have garnered worldwide attention, the lack of adequate charging infrastructure remains a significant hurdle for entering the EV market. To alleviate the drivers' charge anxiety and support the South Korean government's goal of accelerating EV adoption rates, we establish the problem of determining the optimal locations as well as capacities of EV chargers installed within a planned city in South Korea. Interestingly, our study accounts for a group of government regulations governing EV charging station placement, such as the mandatory installation of at least 5% or 2% of the total number of parking spaces in new or old buildings. We identify the drivers and implications of the investment in EV charging facilities. Furthermore, we supplement our analytical results with a case study of a Korean city.

2 - Electrifying Emergency Medical Service Vehicles

Mesut Yavuz, University of Alabama, Tuscaloosa, AL, United States, Ozgur Satici, Iman Dayarian, Muting Ma, Nickolas Freeman

We address the electrification of emergency medical service (EMS) vehicles. Allowing gradual electric vehicle adoption, we (i) develop a dispatching rule to assign a vehicle from a mixed (diesel and electric) fleet of ambulances, (ii) explore the tradeoffs among cost, service level and greenhouse gas emissions, and (iii) prescribe appropriate electrification levels for EMS agencies based on their spatial and demand characteristics. With actual data spanning Alabama in a 3-year period, we show that most agencies could benefit from electrifying at least half of their fleets.

3 - A Column Generation-based Matheuristic to solve the Mixed-Fleet Green Vehicle Routing

Isil Koyuncu, The University of Texas at San Antonio, San Antonio, TX, United States, Mesut Yavuz

This study addresses a mixed-fleet green vehicle routing problem with conventional and electric vehicles. We explore the differences and similarities of route-optimization efforts and their outcomes between the two types of vehicles. Informed by the data from our exploration phase, we design three procedures to be used in a matheuristic. The developed route-based decomposition framework includes column generation and set partitioning components. We computationally experiment on testbeds from the existing literature, and thereby demonstrate that the proposed approach produces results that are comparable with the exact methods that are costly in terms of CPU time.

4 - Sustainable Urban Mobility: Promoting Mobility Equity in Micromobility Sharing Services

Wu Hao, National University of Singapore, Singapore, Singapore, Long He, Sheng Liu

This study investigates the role of subsidy and regulatory policies in promoting mobility equity within micromobility sharing services. By analyzing key performance metrics such as service availability and served demand across different urban areas, we aim to identify effective policy interventions that ensure equitable access and usage. This research offers practical insights for policymakers committed to advancing social equity and sustainability in urban mobility.

Energy Systems Modeling and Optimization

Invited Session

ENRE: Other Energy

Chair: Drew Kassel, University of Texas at Austin, Austin, TX, United States

1 - Impact of experience curves on national adoption of enhanced geothermal power

Wilson Ricks, Princeton University, Princeton, NJ, United States

Enhanced geothermal power is an emerging source of clean, firm electricity generation with prospects for near-term commercialization. In this work we establish a near-term cost baseline for this technology and use an electricity system capacity expansion model with endogenous technological learning-by-doing to explore pathways to large-scale geothermal deployment in the United States over the coming decades. We find that under policies targeting a near-zero or zero-carbon electricity sector by 2050, enhanced geothermal power with an assumed 15% learning rate for subsurface development could grow to become the dominant source of clean firm power on the US grid and supply more than a quarter of total generation. With sufficient learning-by-doing through initial deployments in the resource-rich western US, enhanced geothermal could become economically competitive even in the relatively cooler eastern half of the country. Long-term deployment potential for both enhanced geothermal power and other emerging clean firm technologies is sensitive to the timing and scale of initial deployments in the 2030s, and policies that drive early deployment of these technologies can significantly reduce long-run electricity system costs.

2 - Co-optimization of hydrogen and power production to support long-term grid planning in Texas

Jerry Potts, The University of Texas at Austin, Austin, TX, United States, Sergio Castellanos

Electrolytic hydrogen has emerged as an alternative fuel source for deep decarbonization due to its lack of emissions and capacity for long-duration energy storage. The electricity requirements to satisfy hydrogen demand using electrolysis are likely to have substantial impacts on long-term grid planning. In this work, we develop an open-source capacity expansion model of Texas Interconnection - a region with strong oil and gas infrastructure as well as abundant renewable energy resources that can support large-scale hydrogen adoption - to co-optimize the regional power system and hydrogen sector. We develop a wide set of scenarios to quantify the infrastructure requirements to support hydrogen development under different decarbonization goals and policy incentives. Preliminary results of this model indicate that 44.6 GW of additional transmission capacity and 125 GW of additional renewable capacity are needed to meet the electricity requirements to produce electrolytic hydrogen in a business-as-usual scenario. These capacity requirements more than double when the model is constrained to reach net-zero carbon emissions by 2050. Additional work is underway to further characterize the investment decisions in the hydrogen supply chain in each of these scenarios and to quantify the impacts of sector coupling on the power sector. The results of this analysis elucidate the infrastructure requirements associated with industrial hydrogen demand and can guide stakeholders on how to effectively leverage energy resources and optimize investment decisions to support the development of this emerging market.

3 - PyPSA-USA: A flexible open-source energy system data model and optimization tool for the United States

Kamran Tehranchi, Stanford University, Stanford, CA, United States, Trevor Barnes, Ines Azevedo

PyPSA-USA is a flexible power system data model and optimization tool for the continental United States that can be configured to address modeling questions across resolutions. The PyPSA-USA package provides an interface to flexibly translate between nodal and zonal transmission configurations, prepare generator data, and integrate regional policy constraints with high spatial resolution and temporal scope. The package integrates with climate reanalysis datasets and geospatial terrain datasets, enabling user access to decades of renewable resource availability. We present use-cases for PyPSA-USA in transmission expansion planning and historical operational simulation for model back-casting validation.

4 - Connecting Texas To The National Grids As A Reliability Measure Against Extreme Winter Weather

Drew Kassel, The University of Texas at Austin, Austin, TX, United States, Joshua Rhodes

Grid reliability in Texas is an increasingly highlighted concern due to winter storms and heat waves that have threatened power sector infrastructure and resulted in recent blackout events and calls for demand side conservation One of the most devastating of these events was the North American winter storm, later dubbed “Winter Storm Uri” by the Weather Channel, that froze the region in February 2021. This study focuses on two potential tools which can be used to improve power grid reliability against such winter storms. These two tools are building more firm generation capacity, such as natural gas power plants, and expanding interregional transmission capacity between the Electric Reliability Council of Texas (ERCOT), the Western Electricity Coordinating Council (WECC), and the Eastern Interconnect. Our method leverages open-source modeling tools, such as PowerGenome, pyGRETA, and GenX to synthesize unique zonal grid data, construct a consolidated network of model regions, and simulate different developmental pathways of capacity expansion and operational dispatch while simultaneously optimizing cost and avoiding outage events. Our initial results indicate that it is possible to construct a reliable grid capable of weathering winter storms by building many additional power plants; however, connecting the ERCOT grid to other grids lowers both costs and emissions while providing the same level of reliability in preparation for frequent, extreme, winter storms.

5 - Flexibly-operated carbon capture power plants offer near-term mitigation opportunities with variable renewable energy

Jiacong Li, Tsinghua University, Beijing, China, People's Republic of, Tingliang Zhang, Michael Davidson, Xi Lu

Electrical power system accounts for over 40% of China's total CO_2 emissions, with 56% of electricity generated from thermal power plants in 2022. Flexibly-operated carbon capture and storage (CCS) has been suggested as an effective measure for the decarbonization of coal-fired power plants, with lower capture costs and energy penalty compared with conventional CCS. This study characterizes the interplay of flexible carbon capture power plant (CCPP) with variable renewable energy (VRE) in a large regional grid, and quantifies the system-level benefit of the synergies between flexible CCPP and VRE in environmental and economic aspects, using an improved unit commitment model. Hourly characterization suggests that flexible CCS would decrease its energy consumption in peak-demand periods, and be operated at full load in off-peak periods to take advantage of otherwise curtailed renewable electricity. A number of scenarios installing flexible CCS with different configurations are evaluated. The lowest abatement cost case indicates that installing flexible CCS with 4-h solvent storage and flue gas venting (70% average capture rate) on 10% of coal-fired plants will result in 9.81% reduction of power system total carbon emission in 2030, with a CO_2 mitigation cost of 269 CNY/t (37 USD/t). To fulfill the benefits of flexible CCPP in future power systems, both policy incentives and optimal operation are required.

Optimization Model Analysis and Debugging

Invited Session

Computing Society

Chair: John Chinneck, Carleton University, Ottawa, ON, Canada

1 - Recent Advances in Debugging Tools to Diagnose Ill Conditioning in Linear Programming

Ed Klotz, Gurobi Optimization, Incline Village, NV, United States

Version 1.0 of the gurobi-modelanalyzer open source Python package became available in late 2023. The primary component of the package was a function that provided a row or column based explanation of ill conditioned basis matrices. While the package has had numerous successful use cases, potential challenges remained regarding faster computation time and smaller explanations. This talk will describe the improvements made in version 1.1 of the package that address these challenges.

2 - Ensuring Robustness in Data and Model Results

Robert Randall, Princeton Consultants, Inc., Greenville, SC, United States

Optimization models provide powerful solutions, but their effectiveness hinges on the quality of input data and the rigor of solution validation. This presentation explores methodologies and tools used by Princeton Consultants to guarantee the robustness of real-world models. We'll discuss rigorous input data validation techniques to prevent infeasibilities or model breakdowns. Additionally, we'll delve into the creation of independent solution validators that ensure model outputs consistently adhere to all specified requirements. These strategies provide confidence in model-driven decision-making.

3 - Infeasible Model Analysis In the Optverse Solver

John Chinneck, Carleton University, Ottawa, ON, Canada, Cho Ho (Peter) Lam, Zirui Zhou

Isolating an Irreducible Infeasible Subset (IIS) of constraints is the best way to analyze an infeasible optimization model. The OptVerse solver incorporates very fast algorithms for this purpose. The LP analyzer takes advantage of the presolver to isolate a small subset of constraints for conventional analysis, whether or not the presolve detects infeasibility. The MIP analyzer uses new techniques to very quickly find an IIS that includes the integrality restrictions. Experimental results are given.

4 - A New Reformulated Mixed Integer Linear Programming Model for the Unequal Areas Facilities Layout Problem

Joshua Adu Afari, Missouri University of Science & Technology, Rolla, MO, United States, Abhijit Gosavi, Robert Marley

In complex real-world layout-design problems where department sizes vary, layout optimization techniques have relied on models such as the unequal-areas facility layout (UAFL) model. This model has a mixed integer programming (MILP) nature, whose solutions with branch-and-bound/cut (B-B/C) often lead to poor values of the objective function (the material-handling cost). The literature also suggests employing an aspect-ratio criterion for this MILP, which while fitting each department into a fixed area inevitably alters the departments' dimensions, causing the dimensions to stray from their designed values. To address this challenge, this research introduces a wasted-space-penalized (WASP) model for UAFL, or WASP-UAFL model for short. Unlike the aspect-ratio or the B-B/C approach, WASP-UAFL is a reformulation of the original UAFL model that modifies the objective function and allows for predetermined and unalterable dimensions and areas for departments, while delivering low values for the material-handling cost. Our research proposes numerical solutions to the WASP-UAFL model using three meta-heuristics: backtracking adaptive search, simulated annealing, and the genetic algorithm. We will present numerical results that demonstrate how a simple reformulation of a well-known MILP leads to far superior and easily obtainable solutions in practice for layout problems of realistic dimensions.

Federated Learning and Optimization: I

Invited Session

Computing Society

Chair: Kibaek Kim, Argonne National Laboratory, Lemont, IL, United States

Co-Chair: Farzad Yousefian, Rutgers University, Piscataway, NJ, United States

1 - Federated Adaptive Global Pruning under Model Heterogeneity

Yijiang Li, Argonne National Laboratory, Lemont, IL, United States, Guangji Bai, Kibaek Kim

Federated Learning (FL) has gained significant interest in training AI models in a distributed computing environment benefiting from its capability to maintain the privacy of sensitive data of the participating parties. However, challenges remain in effectively handling of participating parties with heterogeneous computational power, such as edge devices. In this work, we propose a federated framework that involves an adaptive global pruning scheme to enable collaborative training of large models, such as LLMs, on parties with heterogeneous computational power.

2 - Zeroth-Order Federated Methods for Stochastic MPECs and Nondifferentiable Nonconvex Hierarchical Optimization

Yuyang Qiu, Rutgers University, New Brunswick, NJ, United States, Uday Shanbhag, Farzad Yousefian

Motivated by the emergence of federated learning (FL), we design and analyze federated methods for addressing: (i) Nondifferentiable nonconvex optimization; (ii) Bilevel optimization; (iii) Minimax problems; and (iv) Two-stage stochastic mathematical programs with equilibrium constraints (2s-SMPEC). Notably, in an implicit sense, (ii), (iii), and (iv) are instances of (i). However, these hierarchical problems are often complicated by the absence of a closed form expression for the implicit objective function. Research on these problems has been limited and afflicted by reliance on strong assumptions, including the need for differentiability of the implicit function and the absence of constraints in the lower-level problem, among others. We make the following contributions. In (i), by leveraging convolution-based smoothing and Clarke's subdifferential calculus, we devise a randomized smoothing-enabled zeroth-order FL method and derive communication and iteration complexity guarantees for computing an approximate Clarke stationary point. To contend with (ii) and (iii), we devise a unifying randomized implicit zeroth-order FL framework, equipped with explicit communication and iteration complexities. Importantly, our method utilizes delays during local steps to skip calls to the inexact lower-level FL oracle. This results in significant reduction in communication overhead. In (iv), we devise an inexact implicit variant of the method in (i). Remarkably, this method achieves a total communication complexity matching that of single-level nonsmooth nonconvex optimization in FL. We empirically validate the theoretical findings on instances of federated nonsmooth and hierarchical problems including training of ReLU neural networks, hyperparameter learning, fair classification, and Stackelberg-Nash-Cournot equilibrium seeking problem.

3 - Robust Federated Learning with Differential Privacy

Xu Chen, Columbia University, New York, NY, United States, Kibaek Kim

We study the numerical performance of robust federated learning (FL) approaches against noisy data due to differential privacy (DP). DP is a widely-used privacy-preservation technique that statistically guarantees the privacy by adding noise generated from a distribution to model/data. Employing DP in FL a trade-off between data privacy and model performance. We design and numerically experiment a robust FL model with various data set.

4 - Differentially private federated learning via inexact ADMM with multiple local updates

Kibaek Kim, Argonne National Laboratory, Lemont, IL, United States, Minseok Ryu

Differential privacy (DP) techniques can be applied to the federated learning model to statistically guarantee data privacy against inference attacks to com- munication among the learning agents. While ensuring strong data privacy, however, the DP techniques hinder achieving a greater learning performance. In this paper we develop a DP inexact alternating direction method of multipliers algorithm with multiple local updates for federated learning, where a sequence of convex subproblems is solved with the objective perturbation by random noises generated from a Laplace distribution. We show that our algorithm provides epsilon-DP for every iteration, where epsilon is a privacy budget controlled by the user. We also present convergence analyses of the proposed algorithm. Using MNIST and FEMNIST datasets for the image classification, we demonstrate that our algorithm reduces the testing error by at most 31% compared with the existing DP algorithm, while achieving the same level of data privacy. The numerical experiment also shows that our algorithm converges faster than the existing algorithm.

1 - Multi-Objective Optimization Approach for Emergency Evacuation with Pandemic Effects

Razieh Khayamim, FAMU-FSU College of Engineering, Tallahassee, FL, United States, Ren Moses, Eren Ozguven, Maxim Dulebenets

Different types of hazards occur quite often in different parts of the globe. These hazards may cause significant property damages, monetary losses, and human fatalities. For certain types of disasters, populations are expected to evacuate from locations that anticipate the greatest impact. Emergency evacuation is generally challenging, since many people have to evacuate a given area in a short span of time. Lack of proper planning may result in negative externalities (e.g., congestion on evacuation routes, anxiety of evacuees). Furthermore, a frequent occurrence of pandemics makes emergency evacuation planning even more challenging. Rushing to the closest emergency shelter may not be the best choice, because the closest shelters may operate at the capacity level. Overcrowded emergency shelters are expected to have a high risk of virus transmission under pandemic settings. Therefore, this study proposes a new bi-objective optimization model for emergency evacuation planning, aiming not only to minimize the total travel time of evacuees to the assigned emergency shelters but also to minimize the risk of virus transmission in the assigned emergency shelters. A custom multi-objective optimization algorithm is developed to solve the proposed bi-objective optimization model. Various case studies are conducted to demonstrate applicability of the proposed methodology for real-life emergency evacuation scenarios. The findings from this research can be used to better prepare populations for approaching natural hazards and ensure their safety throughout the evacuation process. Moreover, this project will assist with minimizing virus transmission rates in emergency shelters and alleviating the negative impacts of pandemics.

2 - Advancing Carbon Mitigation via U.S. Municipal Green Bond Issuance: Insights from Causal Machine Learning

Dan Li, university of michigan, Ann Arbor, MI, United States

The green bond market provides a vital channel for directing financial resources toward climate-related initiatives that support the Sustainable Development Goals. This study assesses the impact of U.S. municipal green bonds on carbon emissions from 2009 to 2019, considering the complexities of local socio-economic conditions. Employing causal machine learning models, we discerned the effects of increased green bond issuance volume on emission reduction on county level. Our findings reveal notable heterogeneity across regions, with the lagged impact on emission reduction most conspicuous two years post-bond issuance. Within the subgroups analyzed, those residing in counties characterized by long commute times to work appear to benefit most significantly. During the urbanization process, regions experiencing prolonged commute times as a result of city expansion may observe a notably larger impact from green bond issuances in mitigating CO2 emissions. Moreover, our findings highlight the effectiveness of certified green bonds, which undergo environmental outcome verification by assurance companies, in catalyzing efforts to reduce emissions. Last but not least, our study reveals that the introduction of new green bond issuances also tends to result in emission reduction. However, the magnitude of this effect varies significantly compared to the increase in green bond volume in counties already engaged in such issuances. Our research provides novel insights that can inform the development of interventions aimed at strategically allocating resources to regions most likely to derive benefits from targeted environmental measures and urban planning initiatives.

3 - Link Prediction Modelling in Human Trafficking Networks - A Survey

Hasini Balasuriya, University of Louisville, Louisville, KY, United States, Monica Gentili

Link prediction models are vital for analyzing complex networks by predicting missing or future connections and are particularly significant in understanding and combating illicit trafficking networks. Despite numerous surveys on general link prediction modeling, there is a lack of comprehensive studies focusing on the applicability of these models to illicit networks. This study presents the findings from an extensive literature review aimed at bridging this gap by examining the effectiveness of link prediction models in identifying missing links within illicit networks. The objective is to provide a precise, well-organized overview that enhances our understanding of these models' potential in combating illicit activities, and to present preliminary results from the comparison of existing models for link prediction on a human trafficking dataset.

4 - Optimal In-Home Healthcare Shift Scheduling

Evelyn Arrey, The Ohio State University, Columbus, OH, United States, Theodore Allen, Chen Chen

We report on a scheduling app that provides optimal shift assignments for in-home healthcare workers. The problem involves substantial complexity due to various training requirements, legal restrictions, and high variability in both demand and supply with irregular hours. Moreover, in-home healthcare services involve significant face-to-face interactions, and so patients' and employees' subjective preferences are a major factor. Most organizations deal with such complexities by determining assignments manually with schedulers; however, this requires substantial training, involves high time cost in developing schedules, and elevated costs due to typically suboptimal solutions. Our solution involves mathematical optimization, deployed via a mixed integer programming model. The model is inspired by a real-world problem of helping to schedule health aides to reduce overtime expenses and achieve equitable schedules in a non-profit organization; this involves 50 weekly shifts across 40 locations and 30 employees. Our pilot test suggests that our software can reduce much of the overtime costs present in manually configured schedules. We also discuss the scheduling app that integrates our optimization model into the existing system.

5 - Advancing Real-time Pandemic Forecasting Using Large Language Models: A COVID-19 Case Study

Hongru Du, Johns Hopkins University, Baltimore, MD, United States, Jianan Zhao, Yang Zhao, Shaochong Xu, Xihong Lin, Yiran Chen, Lauren Gardner, Hao Frank Yang

Forecasting the short-term spread of an ongoing disease outbreak is a formidable challenge due to the complexity of contributing factors, some of which can be characterized through interlinked, multi-modality variables such as epidemiological time series data, viral biology, population demographics, and the intersection of public policy and human behavior. Existing forecasting model frameworks struggle with the multifaceted nature of relevant data and robust results translation, hindering their performances and providing actionable insights for public health decision-makers. Our work introduces PandemicLLM, a novel framework with multi-modal Large Language Models (LLMs) that reformulates real-time forecasting of disease spread as a text reasoning problem, with the ability to incorporate real-time, complex, non-numerical information—such as textual policies and genomic surveillance data—previously unattainable in traditional forecasting models. Through a unique AI-human cooperative prompt design and time series representation learning, this approach encodes multi-modal data for LLMs. By redefining the forecasting process as an ordinal classification task, PandemicLLM yields more robust and trustworthy predictions, facilitating public health decision-making. The model is applied to the COVID-19 pandemic and trained to utilize textual public health policies, genomic surveillance, spatial, and epidemiological time series data, and is subsequently tested across all 50 states of the U.S. for a duration of 16 weeks. Empirically, PandemicLLM is shown to be a high-performing pandemic forecasting framework that effectively captures the impact of emerging variants and can provide timely and accurate predictions. The proposed PandemicLLM opens avenues for incorporating various pandemic-related data in heterogeneous formats and exhibits performance benefits over existing models.

6 - High-resolution Hotspots of Direct and Indirect Food Instability in SSA.

JUNREN WANG, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Megan Konar, Sitian Xiong

Consistent and stable food supplies are important for ensuring food security in Africa. Climate shocks, varying trade policies, and urbanization create pressures that make stable supplies more of a dream than a reality. In this study, we focus on the specific question, 'Where does the instability come from?' We propose a framework to quickly evaluate food reliability, taking into consideration local demand as well as both domestic and international supply. The scope of this study, analyzing domestic supply at a small administrative level and assessing international contributions on a country scale, is suitable for policy decisions. This work can aid decision-makers in making informed choices regarding strategic food reserves or food aid.

7 - Strategic Optimization of Carbon Credit Incentives: Implications for Urban Travel Patterns and Emission Reductions

Dongyang Zhen, University of Maryland, College Park, College Park, MD, United States, Qingbin Cui

The transportation sector is a major contributor to global carbon emissions, accounting for a significant proportion of the overall environment footprint. In urban areas, the challenge is particularly acute, with dense population and high traffic volumes exacerbating air quality and contributing to climate change.

To address this issue, we leverage carbon credit-based incentive system as a mean to reward reductions in carbon emissions, further influence the travel behaviors. In the system, we develop a bilevel nonlinear programing model to encourage low-emission travel behaviors through the strategic use of carbon credits. The upper level, representing the decision-making of transportation authorities, aims to minimize carbon emissions through the optimal allocation and pricing of carbon credits, along with subsidies for sustainable transportation modes. The lower level reflects the utility maximization of individual travelers, incorporating travel time, cost, carbon credits, capacity constraints, and social influences into their decision-making processes. Given the nondifferentiability of the problem, quasi-Newton methods and stochastic gradient methods are employed to find the approximate solutions, as well as providing robust convergence properties and efficiency in computation.

The model's efficacy and practical implications are tested through numerical experiments utilizing historical trip data from IncenTrip. These experiments investigate the model's application across varied scenarios, reflecting different budget limits, commuter preferences, and urban settings. The experiment results reveal an inherent dilemma between travel time and emission reductions, illustrating the complex interplay between incentivizing sustainable travel and maintaining travel efficiency.

8 - A Digital Twin Model for Sorghum Growth Simulation and Breeding Optimization

Zheng Ni, Oklahoma state university, Stillwater, OK, United States, Maria Salas Fernandez, Lizhi Wang

The increasing demand for resilient and high-yielding crops necessitates advanced breeding methods. This study presents a digital twin model to simulate phenotypic data and provide breeding recommendations based on Genotype x Environment x Management (GxExM) effects for sorghum, a versatile cereal crop with varieties such as Grain (G), Forage (F), Dual Purpose (DP), and Photoperiod Sensitive (PS). The model integrates extensive environmental data, including seven years of hourly weather records and soil conditions from three locations, alongside management practices and pedigree information from 665 fathers and 141 mothers. This enhances the simulation process by analyzing 5,200 records of plot-wise final yield, 6,219 records of individual plant height, and 580 records of dry biomass at different growth stages. Additionally, the model simulates the hourly dry weight of sorghum's leaves, stems, and roots, and predicts final yield based on management practices. Demonstrating robust predictive capabilities, the digital twin model achieves a testing Relative Root Mean Squared Error (RRMSE) of 8% to 10% across diverse conditions. Within our active breeding framework, the model improves the maximum recovery rate by approximately 9% based on simulated genotype input over just two generations, compared to traditional selection strategies. By employing this innovative approach, the research identifies high-yielding hybrids, reducing the time and resources required by conventional methods. This supports efficient hybrid selection and contributes to sustainable agricultural productivity, particularly in identifying high-performing hybrids.

9 - ERGM

Minghua Zhang, University of Wisconsin, Madison, Madison, WI, United States, Justin Boutilier

The private health sector is integral to solving the Tuberculosis epidemic in low-and-middle-income countries. Private practitioner engagement programs can improve tuberculosis outcomes but uncertain data on referral networks and limited resources for engagement require careful selection of practitioners. We propose exponential random graph models and optimization to tackle this issue.

10 - Leveraging Network Science for Optimal Online Vehicle Dispatch on Ride-hailing Platforms

Ruiting Wang, University of California, Berkeley, Berkeley, CA, United States, Jiaman Wu, Scott Moura, Marta Gonzalez

Ride-sharing reduces carbon emissions by lessening private car use. The efficiency at which these platforms reduce emissions hinges on the design of their vehicle dispatch algorithms. This study aims to enhance the request service rate between drivers and riders in ride-hailing platforms by utilizing network science metrics in the shareability network structure. In this work, we first introduce a novel network science metric known as sink proximity within the context of network flow problems, which incorporates future information on the network structures. We then show that sink proximity calculation can be approached as a problem of finding the single source longest path within a directed acyclic graph, thereby addressing the computational complexity of this measure. Last, we develop a Network Science-aided Vehicle Dispatch Algorithm (NetSciVDA) that leverages network science metrics, which effectively addresses vehicle dispatch problems encountered by ride-hailing platforms. Numerical studies demonstrate that NetSciVDA represents a significant advancement in optimizing the dispatch process through the application of network science principles.

11 - Impact of Power Outages Depends on Who Loses It: Equity-Informed Grid Resilience Planning via Stochastic Optimization

Gizem Toplu-Tutay, University of Texas-Austin, Austin, TX, United States, John Hasenbein, Erhan Kutanoglu

This research presents a two-stage stochastic optimization model for flood mitigation investments in the transmission grid, focusing on substation hardening to enhance power grid resilience against extreme weather events. It develops equity metrics based on the affected population and the duration of well-being loss to address the uneven impacts of prolonged power outages on different communities, considering social vulnerabilities. The study also incorporates a justice model inspired by the U.S. government's Justice40 Initiative.

We solve the DC optimal power flow (DC-OPF) problem for each second-stage scenario, using realistic hurricane-induced flood scenarios and a realistic Texas grid for the case study. This study illustrates the tension between minimizing power loss and improving equity among different communities. The results highlight the importance of using a composite objective to enhance the resilience of both the power grid and of disadvantaged communities through investment prioritization and electricity provision. Our research, enriched by a comprehensive sensitivity analysis, offers valuable insights for policymakers, grid operators, and utilities aiming for a more resilient and equitable power grid.

12 - Binary Gaussian Copula Synthesis: A Novel Data Augmentation Technique to Advance Machine Learning for Early Prediction of Dialysis Among CKD Patients

Hamed Khosravi, West Virginia University, Morgantown, WV, United States, Srinjoy das, Abdullah Al-Mamun, Imtiaz Ahmed

The Center for Disease Control estimates that over 37 million US adults suffer from chronic kidney disease (CKD), yet 9 out of 10 of these individuals are unaware of their condition due to the absence of symptoms in the early stages. It has a significant impact on patients' quality of life, particularly when it progresses to the need for dialysis. Early prediction of dialysis is crucial as it can significantly improve patient outcomes and assist healthcare providers in making timely and informed decisions. However, developing an effective machine learning (ML)-based Clinical Decision Support System (CDSS) for early dialysis prediction (i.e., 90 days before initiation) poses a key challenge due to the imbalanced nature of data (i.e., with far fewer cases of dialysis patients compared to non-dialysis CKD patients). This data imbalance hinders the ability of ML models to accurately predict early dialysis. To address this challenge, this study evaluates various data augmentation techniques to understand their effectiveness on real-world datasets. We propose a novel approach named Binary Gaussian Copula Synthesis (BGCS). BGCS is tailored for binary medical datasets and excels in generating synthetic minority data that mirrors the distribution of the original data. BGCS enhances early dialysis prediction by outperforming traditional methods in detecting dialysis patients. It consistently leads to superior performance across models, significantly improving over real data. For the top-performing ML model, Random Forest, BCGS achieved a 72% improvement, surpassing the state-of-the-art (SOTA) augmentation approaches.

13 - SARS-CoV-2 Infection is Associated With An Increase In New Diagnoses of Schizophrenia Spectrum and Psychotic Disorder: A Study Using the US National COVID Cohort Collaborative (N3C)

Ahmed Shoyeb Raihan, West Virginia University, Morgantown, WV, United States, Imtiaz Ahmed

Amid the ongoing global repercussions of SARS-CoV-2, it is crucial to comprehend its potential long-term psychiatric effects. Several recent studies have suggested a link between COVID-19 and subsequent mental health disorders. Our investigation joins this exploration, concentrating on Schizophrenia Spectrum and Psychotic Disorders (SSPD). Different from other studies, we took acute respiratory distress syndrome (ARDS) and COVID-19 lab-negative cohorts as control groups to accurately gauge the impact of COVID-19 on SSPD. Data from 19,344,698 patients, sourced from the N3C Data Enclave platform, were methodically filtered to create propensity matched cohorts: ARDS (n = 222,337), COVID-19 positive (n = 219,264), and COVID-19 negative (n = 213,183). We systematically analyzed the hazard rate of new-onset SSPD across three distinct time intervals: 0-21 days, 22-90 days, and beyond 90 days post-infection. COVID-19 positive patients consistently exhibited a heightened hazard ratio (HR) across all intervals [0-21 days (HR: 4.6; CI: 3.7-5.7), 22-90 days (HR: 2.9; CI: 2.3 -3.8), beyond 90 days (HR: 1.7; CI: 1.5-1.)]. These are notably higher than both ARDS and COVID-19 lab-negative patients. Validations using various tests, including the Cochran Mantel Haenszel Test, Wald Test, and Log-rank Test confirmed these associations. Intriguingly, our data indicated that younger individuals face a heightened risk of SSPD after contracting COVID-19, a trend not observed in the ARDS and COVID-19 negative groups. These results, aligned with the known neurotropism of SARS-CoV-2 and earlier studies, accentuate the need for vigilant psychiatric assessment and support in the era of Long-COVID, especially among younger populations.

14 - Exploring Nutritional Equity in Foodbank Supply Chains

Nowshin Sharmile, North Carolina A&T State University, Greensboro, NC, United States, Lauren Davis

Food insecurity, defined as insufficient access to food for a healthy and active life, affected approximately 12.8% of U.S. households in 2022. A concerted effort from both the government and non-government organizations is underway to address this challenge in the United States. This study centers on the Foodbank of Central and Eastern North Carolina (FBCENC), a nonprofit hunger relief organization pivotal in collecting and distributing food donations to local agencies serving individuals in need. However, despite the critical role of food banks, nutritional considerations are often overlooked. To address this gap, the study employs the Healthy Eating Research (HER) Nutrition Guideline, categorizing nutrition types (Red, Yellow, and Green) to assess and enhance the nutritional equity of the current distribution system. A linear programming model is proposed, and equity and effectiveness are adopted as the performance measure. The study aims to develop a model strategically reducing nutritional disparities across the network. By incorporating HER guidelines and emphasizing equity in distribution, this research contributes to the broader objective of creating a more nutritionally equitable response to food insecurity within the non-profit sector.

1 - Integration of Object Detection Machine Learning and Geospatial Information for Improved Power System Planning

Maxwell Miller, Carleton University, Ottawa, ON, Canada, Ahmed Abdulla

Decarbonization of transportation and heating requires electrification, entailing significant upgrades to electricity distribution infrastructure. It is rare for local distribution companies to make publicly available maps of their systems that enable power flow simulations at the distribution level. Here, we map local distribution networks using a combination of machine learning models and geospatial intelligence. We leverage object detection machine learning models, an area of growing interest and work. Current models claim an F1 score of 0.764; however, these models focus on mapping much larger transmission infrastructure. The challenge of mapping smaller distribution infrastructure remains unresolved. This project develops widely applicable methods to improve F1 scores when mapping local distribution networks using data-filtering (focusing on feasible pole locations), and context maps. The latter integrate real-world logic with model predictions by weighting pole probabilities based on their relative positions to landmarks like roads and houses. Using Cornwall, Ontario, Canada as a test site, mapping makes use of DRAPE remote sensing imagery segmented with ArcGIS as training data for a python-based machine learning model. The model outputs a geospatial inferred dataset of distribution poles, tuned with a human-in-the-loop process. By combining this map with energy demand simulations developed elsewhere, power system optimization at the distribution level is possible. Future research will focus on power system optimization, accounting for supply at the distribution level with increased granularity and generalizing the analytical framework for other uses.

2 - The *FastMap* Redistricting Algorithm: Promoting Fair Elections with Optimized Political Districts

Matthew Petering, District Solutions LLC, Milwaukee, WI, United States

On January 12, 2024 seven proposals for Wisconsin's legislative districts were submitted to the Wisconsin Supreme Court in the case *Clarke v. Wisconsin Elections Commission*. One was generated by a computer algorithm, and six were created by expert human mapmakers. In this presentation, we examine a major development from the case: the map proposal generated by the *FastMap* algorithm significantly outperformed the other proposals. Relevant background information, an algorithm summary, and map visualizations/comparisons are provided. The case likely marks the moment when computer algorithms surpassed humans in overall mapmaking ability. Going forward, algorithmic mapmaking will enhance American democracy by ensuring that congressional, state legislative, and local election districts better reflect constitutional requirements, the will of the voters, and other criteria specified by courts and legal teams.

3 - p-Hacking and Publication Bias in Information Systems Research

Minh Nguyen, Michigan State University, East Lansing, MI, United States

p-hacking and publication bias are significant issues within the scientific community. This study examines their prevalence in quasi-experimental causal inference methods specifically within information systems research. Analyzing nearly 3,000 tests from over 300 articles published in the top seven Information Systems journals, we find notable variation in the prevalence of p-hacking and publication bias across different methods. Evidence of p-hacking is present at the 5% and 10% significance levels in Difference-in-Differences and Instrumental Variables methods, raising concerns about the reliability of results reported using these methods. Conversely, Regression Discontinuity and Synthetic Control methods do not exhibit such evidence. Importantly, our findings indicate that the review process helps address these issues, mitigating concerns about published research.

4 - A region-dependent e-hailing service pricing strategy for rapid massive evacuation

HANG SU, Tongji University, Shanghai, China, People's Republic of, XIAONING ZHANG

Faced with growing and unpredictable passenger travel demands in urban areas, e-hailing services are crucial for regional transportation. Effective pricing and scheduling strategies are urgently needed to optimize vehicle supply and enhance evacuation efficiency during mass gathering events. Based on the Macroscopic Fundamental Diagram (MFD), this paper introduces a mathematical model to characterize the time-varying evolution of e-hailing vehicles within a two-region transport system. Considering drivers' repositioning decisions and passengers' demand dynamics, the model facilitates a region-dependent pricing strategy for rapid massive evacuation. Results from the experimental study indicate that (1) the region-dependent pricing strategy consistently leads to a shorter total evacuation time, more stable traffic conditions, and reduced passenger waiting time for dispatching; and (2) despite the higher generalized wage for drivers and increased generalized cost for passengers, the region-dependent pricing strategy effectively allocates a more balanced distribution of vacant vehicle supply under mass gathering events.

5 - Does Virtual Take Longer? An Empirical Investigation of Service Time in Telemental Health

Yupu Sun, University College London, London, United Kingdom, Ersin Korpeoglu, Lina Song

Telemedicine visits, characterized by synchronous interactions between patients and providers, have witnessed a significant surge during the COVID-19 pandemic. To better understand how telemedicine impacts the efficiency of healthcare delivery, we examines the causal relationship between telemedicine adoption and service time, using the patient-level data for psychology visits from Medicare and private insurance claims in the U.S.. We employ an instrument variable model with a control function approach by utilizing the availability of 5G broadband coverage in the area as an IV. We see that telemedicine adoption significantly decreases service time in psychiatry for private insurance patients, while it significantly increases service time for the Medicare insurance case. We further find that telemedicine is consistently correlated with shorter service times for patients under 65. We posit that our observations hinge on the interaction of two opposing drivers: limited computer literacy and increasing access to care. Evidence shows that telemedicine-only patients have more monthly visits than in-person-only patients under both insurance types. The former effect drives the result for the older population whereas the latter effect drives the result for the younger population. Our study makes important contributions by providing a insight into how telemedicine use affects service time. Practitioners should be mindful of patient age when determining whether to provide virtual or face-to-face services. In particular, transforming mental health visits to online for the elderly population may put some extra strain on healthcare operations due to increased service times and visit frequencies.

6 - A multi-method approach to identifying necessary and sufficient conditions of information asymmetry in supply chain networks

Soode Vaezinejad, University of Rhode Island, Kingston, RI, United States, Dara Schniederjans

Supply chains involve various actors interconnected by finance, materials, and information flows. Information asymmetry arises when one of these actors has more or better information than another, leading to market inefficiencies and other problems. This study conducts a systematic literature review and a Delphi study with industry experts to identify conditions that cause information asymmetry in supply chains. Then, using Necessary Condition Analysis (NCA) and fuzzy-set Qualitative Comparative Analysis (fsQCA), this study identifies necessary conditions and sufficient configurations of conditions that cause information asymmetry at the interorganizational level in supply chains. This study enhances theoretical understanding and provides practical insights.

7 - Let Me Know What Appeals to You: A Flow-Inspired Bayesian Dynamic Interest Model

Jinnan Huang, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Jiapeng Liu, Xiuwu Liao, Zice Ru

We introduce a novel, interpretable Bayesian dynamic interest model inspired by flow theory to understand user behavior and content consumption interests on short video platforms (SVPs). Our approach integrates a Gaussian Mixture based Hidden Markov Model (GMM-HMM) and a Topic Model within a full Bayesian framework to jointly model user behavior patterns and content consumption interests, addressing the challenge of predicting complex user interests on SVPs. This method reveals distinct user behavior stages and successfully captures the dynamic evolution of content consumption interests across these stages. It provides platform managers with interpretable insights into user interests, helping them understand the relationships between user stickiness, active states, and content preferences. To make our approach scalable to large dataset, we design an efficient variational inference algorithm for model inference. We utilize real data from NetEase Cloud Music Cloud Village, a renowned music streaming community in China, and verify the effectiveness of the proposed model through multiple comparative experiments.

8 - Optimizing Stochastic Sustainable Supply Chain Networks for Reusable Products

Amir Hossein Sadeghi, NC State University, Raleigh, NC, United States, Rob Handfield

This study addresses the problem of supply chain network design for reusable products in a single-vendor, multi-product, multi-retailer, with a focus on economic and environmental sustainability. The objective is to efficiently manage product reuse and recovery, considering various constraints such as budget limitations, storage capacity, and the number of orders. To capture the uncertainty associated with these constraints, a stochastic formulation is adopted to provide a more realistic representation of the problem. A nonlinear mathematical model is proposed to formulate the stock management problem and it is solved using SAS 9.4. This research contributes to the field of sustainability by offering a comprehensive framework for managing stock of reusable products, considering both economic and environmental dimensions. The proposed mathematical model and metaheuristic approaches, provide practical tools for companies to optimize their stock management strategies and promote sustainable practices in product reuse and recovery.

9 - On the Robustness of Spectral Algorithms for Semirandom Stochastic Block Models

Naren Manoj, TTIC, Chicago, IL, United States, Aditya Bhaskara, Agastya Jha, Michael Kapralov, Davide Mazzali, Weronika Wrosz-Kaminska

In a graph bisection problem, we are given a graph G with two equally-sized unlabeled communities, and the goal is to recover the vertices in these communities. A popular heuristic, known as spectral clustering, is to output an estimated community assignment based on the eigenvector corresponding to the second-smallest eigenvalue of the Laplacian of G. However, spectral clustering is known to be non-robust to model misspecification. Techniques based on semidefinite programming have been shown to be more robust, but they incur significant computational overheads. In this work, we study the robustness of spectral algorithms against semirandom adversaries. Informally, a semirandom adversary is allowed to ``helpfully'' change the specification of the model in a way that is consistent with the ground-truth solution. Our semirandom adversaries in particular are allowed to add edges inside clusters or increase the probability that an edge appears inside a cluster. Semirandom adversaries are a useful tool to determine the extent to which an algorithm has overfit to statistical assumptions on the input. On the positive side, we identify a wide range of semirandom adversaries under which spectral bisection using the unnormalized Laplacian is strongly consistent, i.e., it exactly recovers the planted partitioning. On the negative side, we show that in many of these settings, normalized spectral bisection outputs a partitioning that makes a classification mistake on a constant fraction of the vertices. Finally, we demonstrate numerical experiments that complement our theoretical findings.

10 - An Extension of Harsany's Linear Tracing Procedure for Selecting a Sequential Equilibrium

Lingxuan Tang, City University of Hong Kong, Kowloon, Hong Kong, Chuangyin Dang

As a strict refinement of subgame perfect equilibrium, the concept of sequential equilibrium was established by Kreps and Wilson (1982) for extensive-form games with perfect recall. The selection of an equilibrium is indispensable for applications. It is well known that Harsanyi's linear tracing procedure plays a central role in the selection of a Nash equilibrium. This paper extends Harsanyi's linear tracing procedure to selecting a sequential equilibrium by introducing an extra variable that decreases from one to zero. However, the starting point may not be uniquely determined. To address this concern, we construct a convex-quadratic-penalty agent extensive-form game by incorporating convex-quadratic-penalty terms into payoff functions of the agents. Through this formulation, we establish the existence of a smooth path that starts from an arbitrary totally mixed behavioral strategy profile and gradually converges to a sequential equilibrium as the extra variable approaches zero. Numerical results show that the differentiable path-following method is effective and efficient.

11 - Probabilistic Pruning for Branch and Bound: An example on TSP

John Becker, USNA, Annapolis, MD, United States, Rajan Batta, Claudio Contardo

This presentation introduces the probabilistic pruning method for branch and bound for reducing the time required to accept satisfactory solutions. The proposed method is tested in instances of the traveling salesman problem (TSP) to demonstrate its effectiveness. The foundation of probabilistic pruning is sampling the distribution of solutions which can occur below a given vertex of the search tree. This distribution is used to calculate the probability the incumbent solution already satisfies the gap requirement set forth by a user. If the probability is sufficiently high, the vertex is trimmed. Three variants to the pruning method are developed and tested against each other and classic branch and bound. The variants s are tested on 20-40 city TSP instances across varying probability and desired gap thresholds. The methods are also tested with a hot and cool start on each instance, probability setting, and desired gap setting. The results indicate the desired gap is almost always achieved across all probability values, and the variants can reduce search runtimes in many settings.

12 - Driving Equity Crowdfunding Success: Insights from Startup Characteristics

Emily Mo, University of California, Berkeley, Berkeley, CA, United States, Xiahua Wei

Equity crowdfunding (ECF) has emerged as a significant fundraising avenue for startups. Understanding the factors driving ECF is crucial for startup success. This study aims to identify potential factors influencing investor decisions and provide entrepreneurs with strategies to maximize their investment potential when designing campaigns. Toward this goal, we collected and analyzed campaign-level data from a leading ECF platform in the U.S., including business background information, financials, and founder demographics. Our analysis indicates that startups with higher fundraising goals, larger amounts of cash on hand, and greater net losses, as well as those with smaller valuation caps, tend to attract more funding from investors. Interestingly, factors such as the founder's gender, race, and education, along with the startup's geographic location and technological focus, demonstrated little correlation with the amount of funds raised. These findings offer insights into designing effective ECF campaigns, suggesting that entrepreneurs may benefit from setting larger funding goals and modest valuation caps. Future research will extend this study by tracking data over time, examining various stages of the fundraising process, and cross-validating findings across different ECF platforms.

13 - Multi-Objective Optimization for Shared-Ride Automated Mobility-on-Demand Services

Cheng Zhang, Texas A&M University, College Station, TX, United States, Min-Ci Sun, Luca Quadrifoglio

This study conducts a quantitative examination of shared-ride automated mobility-on-demand services (SRAMODS), highlighting potential advantages compared to non-shared rides. With the proliferation of robotaxis in certain urban areas, strategic planning and evaluating the potential for shared rides are crucial. Unlike traditional taxis, the SRAMODS system employs a centralized controller to assign vehicles, enabling a more systematic approach to vehicle allocation.

The study introduces a multi-objective model for shared-ride robotaxi, addressing the perspectives of on-site, in-vehicle riders, and robotaxi operators by minimizing waiting time, travel time, and detour distance at each pairing epoch. The proposed model can handle both ad-hoc and pre-booked riders, dynamically matching riders within each epoch, with each robotaxi accommodating up to 4 riders simultaneously.

The model is verified using conventional taxi data from Chicago. Results indicate that the weighting of waiting time, travel duration, and detour distance significantly impacts the final solutions. Prioritizing one objective improves its performance but compromises others. Equal weighting of waiting time and travel time minimizes total trip time, while balanced weighting across all objectives serves more riders. Additionally, higher vehicle capacity enhances pairing efficiency and reduces average travel distance, especially with limited robotaxis in the city.

Rider-matching models have been analyzed within the contexts of dial-a-ride, ride-hailing, and ride-sharing services. With the trend towards robotaxis, it is critical to customize models for automated mobility-on-demand services. This study investigates the incorporation of multiple perspectives, bringing attention to the benefits for all stakeholders and facilitating a smarter approach to robotaxi services.

14 - Patch-based representation learning for time-series anomaly detection

Jinju Park, Sungkyunkwan University, Suwon, Korea, Republic of, Seokho Kang

Time-series anomaly detection involves identifying anomalous patterns within time-series data, achieved by learning solely from previously observed normal patterns. Recent research advances in this field have focused on capturing long-term dependencies using large transformer architectures. Although they have proven effective, capturing long-term dependencies may not necessarily benefit anomaly detection performance in many real-world applications where time-series data appear as repetitions of regular patterns, whereas anomaly patterns break this regularity. In this study, we propose a time-series anomaly detection method based on patch-based representation learning. We use a simple representation model that takes a patch—a short segment of the time-series—as input, instead of the entire time-series. In the training phase, the model is trained using a learning objective comprising two loss functions: contrastive loss and pretext loss. The contrastive loss aims to make representations invariant to trivial noise or shifts by encouraging slightly time-shifted patches to be close together while keeping other patch pairs far apart in the representation space. The pretext loss aims to enrich representations to reflect positional relationships among patches by predicting whether a given pair of patches is adjacent. In the inference phase, whether a query is anomalous is determined based on its distance from the nearest patches in the training data and the prediction accuracy of its relative position against the timely-adjacent patch. We demonstrate the effectiveness of the proposed method on benchmark datasets.

15 - What does it take to be 100% Renewable

Eina Ooka, The Energy Authority, Bellingham, WA, United States

As wind and solar power increasingly saturate the energy grid, integrating energy storage solutions becomes essential to continue the expansion of green energy. This study utilizes linear programming to identify the optimal combination of renewable energy sources and storage systems necessary for achieving a 100% renewable energy system, its economic burden, and the benefit of load flexibility.

Using historical wind and solar data, we capture realistic energy drought situations in the US Southwest region. We evaluate multiple layers of battery storage with different durations to determine the most effective configurations. We also find that small percentages of load shedding significantly reduce the required capacities for energy generation and storage.

The results provide strategic insights into cost-effective pathways for scaling up renewable energy deployment and guide informed decision-making in achieving a sustainable and economically viable energy future.

16 - New Perspectives in Online Contract Design

Shiliang Zuo, UIUC, Savoy, IL, United States

I study the contract design problem from an online learning perspective. I study three settings. In the first setting, I study the problem of learning the optimal learning contract when the outcome is binary. I show that the problem is in fact equivalent to dynamic pricing with unknown demand curve. In the second setting, I study the multitask principal-agent problem. I first show that under certain conditions, the optimal contract is uniform across hetergeneous agents whose productivity and cost function may differ. Further, I identity the problem of finding the optimal contract as a instrumental regression problem and give efficient algorithms for learning the optimal contract. In the third setting, I study the team production setting. I introduce the notion of induced production function, and show how the principal can find the optimal profit sharing rule via solving a family of convex programs.

17 - dynamic routing and pricing for meal delivery using a deep Q learning method

Chun-wei YANG, City university of hong kong, Hong Kong, Hong Kong

On-demand meal delivery platforms require efficient routing and pricing to maximize operational efficiency and customer satisfaction. This study presents a dynamic framework for meal delivery using deep Q-learning. Our approach adapts in real-time to changing conditions and customer demands. By modeling the problem as a Markov decision process (MDP), we use deep reinforcement learning to optimize pricing and routing decisions dynamically. Our method incentivizes customers to select diffenent meal delivery options to balance load and improving efficiency. Computational experiments show our dynamic method significantly outperforms conventional strategies, increasing both revenue and orders fulfilled.

18 - Prediction-Based Traffic Signal Control Algorithm for Mixed Autonomous Vehicle Traffic Environment

Jaewon Choi, Pohang University of Science and Technology, Pohang, Korea, Republic of, Wonjae Lee, Hyungjun Park, SunJin Han, Dong Gu Choi

A robust traffic signal control system is required to accommodate the coexistence of conventional and autonomous vehicles. To achieve such system, it is necessary to predict traffic volume by considering the characteristics of autonomous vehicles. Then optimal signal decisions can be made based on the predicted traffic volumes, thereby enhancing traffic operational efficiency. We focus on developing a method to predict the traffic inflow and determine the optimal signal cycle. We perform a simulation experiment in a single intersection environment and show effective traffic management compared to the non-predictive control approach.

19 - Optimizing Inbound Logistics in Aurubis

Sofiya Onyshkevych, Aurubis AG, Hamburg, Germany, Christos Galanopoulos, Leonardo Assis, Bianca Springub

Aurubis is a leading global supplier of non-ferrous metals and one of the largest copper recyclers worldwide. Ensuring the timely receipt and processing of raw materials and components is crucial to maintaining smooth production flows. To always have enough materials available, it is essential to ensure smooth supply chain operations, including efficient planning of the unloading of the vessels and their delivery to the destinations.

To address these challenges, we have developed a data-driven optimization tool designed to support Aurubis' SCM team in daily operational planning. Our tool employs a Mixed-Integer Linear Programming (MILP) model formulated using Pyomo, incorporating various constraints on materials, unloading destinations, and different operational rules.

The primary objective of our tool is to minimize waiting times and associated costs, thereby enhancing operational efficiency. The cost function within our model accounts for multiple types of costs and incorporates detailed operational complexities. Given the intricate nature of vessel assignment and sequencing, our goal is to provide a user-friendly tool that would be used in the company regularly and efficiently.

This tool not only simplifies the assignment and scheduling processes but also optimizes the overall supply chain performance, ensuring that materials are available when needed without incurring unnecessary costs. Our presentation will delve into the development, implementation, and practical applications of this optimization tool within Aurubis' operations.

20 - Assessing Concordance of Real-Time Self-Reported Pain Events between Patients with Advanced Cancer and their Family Caregivers Using a Remote Health Monitoring System

Mina Ostovari, University of Virginia, Charlottesville , VA, United States, Natalie Crimp , Sarah Ratcliffe , Virginia LeBaron

This study proposes an analytic approach to examine the concordance (agreement) between cancer pain reported by patients and their family caregivers using real-time data collected through the Behavioral and Environmental Sensing and Intervention for Cancer (BESI-C), a remote health monitoring system designed for managing advanced cancer pain at home, particularly in rural areas. Unlike previous cross-sectional studies focusing on either patient or caregiver perspectives, this method captures dynamic symptom fluctuations and compares both viewpoints.

Patient-caregiver dyads recruited from a palliative care clinic used the BESI-C app on their smartwatches to independently record patient pain as it occurred. Patient-reported pain events were considered the reference point and clustered together if marked within a 40-minute window. Pain events recorded by a caregiver within a patient cluster or 30 minutes before or after were considered concordant with that cluster. For each pain event/cluster, we considered three scenarios: 1) Recorded by the patient with no overlapping caregiver event, 2) Only recorded by the caregiver, and 3) Recorded by the patient and overlapped with a caregiver event. The agreement was calculated by dividing scenario three occurrences by the total number of cases across all scenarios.

The sample included 12 dyads. The highest level of agreement was 60%, with all other deployments showing less than 50% agreement.

This proposed approach facilitates research on improving cancer pain management by enabling comparisons of symptom experiences between patients and their caregivers. Future work will explore the concordance relationship with quality-of-life metrics to design tailored interventions that alleviate symptom burden.

21 - Fortifying Distribution Network Nodes Subject to Disruptions

Pelin Kesrit, Texas A&M University, College Station, TX, United States, Bahar Çavdar, Joseph Geunes

We consider a distribution network for delivering a natural resource or physical good to a set of nodes, each of which serves a set of customers, in which flow disruptions may occur at one or more nodes. Each node receives flow through a path from one or more source nodes, implying that a node experiences a disruption if a disruption occurs at one or more nodes on each path from a source node. All nodes in the network are subject to a future disturbance of an uncertain degree of severity, and we assume we can quantify the degree of severity, and that it follows some well-defined probability distribution. For each node in the network, we wish to determine a fortification level that enables the node to withstand a disturbance up to some level of severity. The cost of fortification is nondecreasing in the maximum-severity fortification level chosen, and we wish to maximize the expected number of customers who do not experience a disruption following the occurrence of a disturbance, given a limited fortification budget. We formulate this problem as a mathematical program, characterize useful properties of optimal solutions, and provide methods for determining optimal fortification levels under various assumptions on the probability distribution of the disturbance severity and the network structure.

22 - Low-carbon Optimal Dispatch of Integrated Power and Transportation System via Distributed Approach

Zepeng Li, Tsinghua-Berkeley Shenzhen Institute, Tsinghua University, Shenzhen, China, People's Republic of, Qiuwei Wu, Litao Zheng, Xuan Zhang

The rapid proliferation of electrical vehicles (EV) contributes to carbon reduction in the transportation sector. However, it also complicates the management of power distribution system (PDS) and transportation system (TS). To better manage the two systems, a low-carbon optimal dispatch scheme for the integrated power and transportation system (IPTS) is proposed. Carbon emissions from the TS and PDS are quantified using specific models. A series of model reformulation methods are employed to transform the original non-convex model into a tractable one. Then the fast adaptive alternating direction method of multipliers (ADMM) based distributed approach is developed to solve the problem to protect the privacy of the PDS and TS. Case studies illustrate the effectiveness of the proposed scheme in achieving low-carbon optimal dispatch of IPTS and the superiority of the fast adaptive ADMM based distributed approach in computation performance.

23 - The impact of Paid Membership Programs on Customer Purchases

Yuchen Xu, Shanghai University of Finance and Economics, Shanghai, China, People's Republic of, Yuan Chen

Despite the widespread belief in the importance of paid membership programs, their effectiveness and profitability are still unclear. This study utilizes data from a prominent Chinese offline retailer to examine the causal effect of such programs on customer purchases. Through a quasi-experimental design incorporating a staggered difference-in-differences approach, the research investigates the impact of paid memberships on purchase amount, frequency, and average order amount. The findings show a significant positive effect on all three purchasing metrics, indicating the effectiveness of paid membership programs in increasing retail sales and customer engagement. The analysis further segments customers into low-frequency, general, discount-sensitive, and active categories, discovering that the paid membership program is particularly effective in increasing purchases among low-frequency customers. It also highlights the role of in-store services offered through offline paid memberships in affecting customer purchases. Moreover, the study explores the proxy profitability of the program and finds that each paid member can bring a positive revenue for the retailer. The study also conducts some robustness checks including parallel trend test, falsification test and causal forest algorithm as an alternative method. The research contributes valuable insights into the strategic implementation of paid membership programs in the retail sector, emphasizing their potential to enhance retailer competitiveness and profitability.

24 - Supply Chain Coordination Using Put-Option Contracts with Cooperative Advertising: A Supplier-Led Stackelberg Game

Muhammad Mudassar SHARIF, Lingnan University, Hong Kong, Hong Kong, Mingming Leng

This article deals with the coordination issue of a two-echelon supply chain facing additive promotional efforts dependent stochastic demand in the presence of cooperative advertising. Coordination becomes more challenging when the end consumer's demand is promotional dependent. As a Stackelberg follower, the retailer determines the order quantity, put-option quantity, and promotional efforts before the selling season starts. First, we proposed a put-option contract to coordinate the promotional efforts and ordering decisions of the retailer. However, we found that the put-option contract alone fails to coordinate the ordering and efforts decisions of the retailer. Instead, a put-option contract in the presence of cooperative advertising, with two parameters - option price and participation rate, can achieve supply chain coordination.

We also discussed the impact of the proposed contract on the optimal ordering and promotional effort decisions of the retailer and obtained the optimal option price and participation rate of the supplier in decentralized settings. By comparing the proposed coordinated contract with the decentralized settings and a wholesale price contract as a benchmark, we showed that the given contract improves the profits of the retailer, supplier, and leads to win-win outcomes for both the retailer and supplier.

Finally, we provided sensitivity analysis to discuss the impact of non-contract parameters and the randomness of demand on the optimal decisions, profits of the chain members, and the efficiency of the coordination and drawn some important managerial insights.

Keywords: Supply chain coordination; cooperative advertising; put-option contract; additive stochastic demand; promotional efforts; participation rate; Stackelberg game

25 - Evaluating the Potential of Generative AI for Data Storytelling: Insights from a Survey Study

Vinayaka Gude, Elon University, Elon, NC, United States, Andini Safitri, Yazan Kakish

Data storytelling synthesizes narrative techniques and data visualization to clarify complex information for diverse audiences. With the advent of Generative AI, this practice has seen substantial innovation, allowing for the automation of storytelling elements and enhancing data-driven decision-making. Today, the integration of these technologies spans text and visual content generation; however, challenges remain in accurately replicating intricate details and mitigating biases. The current study explores the strategic use of Generative AI tools in data storytelling, focusing on the optimal timing and approaches for their employment and evaluating the user's perception of the overall applicability of LLM models for the storytelling process. Our research questions aimed to understand how prior experience with data visualization and Generative AI tools influences attitudes towards their adoption and how hands-on experiences alter perceptions of their utility. Our findings suggest that individuals with prior experience using Generative AI will likely continue utilizing these tools for data storytelling, especially since they are helpful in the initial, more ambiguous stages of story development. We observed a significant shift in user likelihood to use these tools from before to after hands-on experience, highlighting the crucial role of proper education and guidance in maximizing their effectiveness. This research contributes to the ongoing dialogue on integrating advanced AI tools into additional data storytelling practices, aiming for a future where these technologies support storytelling's technical and creative aspects.

26 - Driving Sustainability - Route Optimization for Campus Composting Operations at Texas State University

Clara Novoa, Texas State University, San Marcos, TX, United States, Yeasir Iqbal, Luis Pardo, Rakesh Chowdhury

Bobcat Blend, a pioneering waste management program at Texas State University initiated in 2009. The program has expanded to manage various organic wastes, producing high-quality compost. Despite its success, Bobcat Blend faces challenges in optimizing its waste collection and transportation operations due to limited resources and a single vehicle capacity. This study develop an optimized routing strategy to enhance operational efficiency and sustainability by satisfying pickup and delivery simultaneously. The model minimizes transportation costs and maximizes efficiency by considering customers geographical distribution, stochastic demand, and vehicle capacity constraints. Computational results generated through the node-based and arc-based formulation reflect the efficiency in route design and adaptability to different demand scenarios. The optimal routing strategy enhances the program's capacity to divert organic waste from landfills, reduces environmental impact and operational costs, supports Texas State University's sustainability goals and offers a scalable model for other institutions. This study also underscores the potential of optimization models in advancing sustainable waste management practices, ensuring timely waste collection.

27 - Evaluating the Effects of Introducing Flexible Meeting Points to Ridesharing System in Large Urban Area

Cheng Zhang, Texas A&M University, College Station, TX, United States, Luca Quadrifoglio, Min-Ci Sun

Ridesharing has emerged as an effective strategy to meet the increased travel demand caused by the rapid growth of populations, and the trend towards urbanization in large metropolitan areas. However, traditional ridesharing system may increase traffic congestion, gas emissions, and passengers' discomfort due to detours for pickups and drop-offs.

To mitigate the adverse effects of travel detour, we advocate for a novel integration of flexible meeting points within the ridesharing system. This approach provides direct travel route from a pickup meeting point to drop-off locations, eliminating unnecessary travel distance. Meeting points can be located at the participants' origin and destination or within an acceptable distance from them.

Our study established flexible meeting points based on the spatial and temporal information of riders and drivers. We adopt a mixed integer linear programming formulation and simultaneously consider multiple objectives, including reducing the total mileage of travel detour, potential waiting time, and walking time between origin/destination and meeting points, while maintaining acceptable level of comfort for passengers and drivers. Simulation experiments utilize large-scale travel demand dataset from peak hours in urban districts of Chicago to validate our methodology. The experiment results show that the efficiency of transportation system is improved by introducing flexible meeting points to ridesharing system, compared to traditional taxi services and door-to-door shared ride services. This research intends to offer a strategy and detailed information for planners and policy makers to intervene by incentivizing a conversion, even if partial, of improving the system-wide ridesharing services.

28 - Multi-level Traffic-Responsive Tilt Camera Surveillance through Predictive Correlated Online Learning

Zilin Bian, New York University, Brooklyn, NY, United States

In urban traffic management, the primary challenge of dynamically and efficiently monitoring traffic conditions is compounded by the insufficient utilization of thousands of surveillance cameras along the intelligent transportation system. This paper introduces the multi-level Traffic-responsive Tilt Camera surveillance system (TTC-X), a novel framework designed for dynamic and efficient monitoring and management of traffic in urban networks. By leveraging widely deployed pan-tilt-cameras (PTCs), TTC-X overcomes the limitations of a fixed field of view in traditional surveillance systems by providing mobilized and 360-degree coverage. The innovation of TTC-X lies in the integration of advanced machine learning modules, including a detector-predictor-controller structure, with a novel Predictive Correlated Online Learning (PiCOL) methodology and the Spatial-Temporal Graph Predictor (STGP) for real-time traffic estimation and PTC control. The TTC-X is tested and evaluated under three experimental scenarios (e.g., maximum traffic flow capture, dynamic route planning, traffic state estimation) based on a simulation environment calibrated using real-world traffic data in Brooklyn, New York. The experimental results showed that TTC-X captured over 60\% total number of vehicles at the network level, dynamically adjusted its route recommendation in reaction to unexpected full-lane closure events, and reconstructed link-level traffic states with best MAE less than 1.25 vehicle/hour. Demonstrating scalability, cost-efficiency, and adaptability, TTC-X emerges as a powerful solution for urban traffic management in both cyber-physical and real-world environments.

29 - A Machine Learning-Based Method for Reliability Improvement of All-Terminal Networks

Seyyed Farid Hashemian, University of Arkansas, Fayetteville, AR, United States, Jose Azucena, Haitao Liao, Ed Pohl

Since the effort of calculating the exact all-terminal reliability grows exponentially, approximation methods are often applied. The performance of such data-driven models is highly dependent on the approximation model. In this work, we consider using a GNN model and compare it with previouse approximation models. Moreover, we implement a DRL algorithm to solve the network reliability improvement optimization problem which leverage the all-terminal network reliability estimation.

30 - Dynamic penalty-based dispatching for optimal EMS response times: A heuristic approach

Sevin Mohammadi, Columbia University, New York, NY, United States, Andrew Smyth

The dispatching process is inherently sequential and dynamic, with each decision impacting future resource availability. Simply sending the closest idle unit without considering the supply and demand in the unit's catchment area may not be optimal. This study introduces a dynamic penalty metric assigned to each idle ambulance, penalizing dispatches from regions with high demand and lower coverage. Dispatch decisions balance travel time and penalties for low-priority calls. We evaluated this approach through discrete event simulation in two experiments of varying sizes. First, a reinforcement learning agent trained in a small-scale experiment revealed that a greedy policy is myopic. Subsequent experiments showed that the heuristic policy, which balances penalties and travel time, outperformed the greedy policy. We further tested the heuristic policy on EMS responses in Manhattan, New York. The results, comparing empirical cumulative distribution functions (ECDF) of episode means for response times as well as the episode fractions of response times exceeding a certain time, indicated that the heuristic method provided more reliable and faster responses for high-priority calls. Specifically, 90\% of episodes under the heuristic policy had mean response times below 6 minutes, compared to 75\% under the greedy policy. Overall, the heuristic method demonstrated superior performance in minimizing response times and variability for high-priority emergencies.

31 - Online Optimization with Rational Agents

Owen Shen, MIT Operation Research Center, Cambridge , MA, United States, Patrick Jaillet

We analyze online optimization in dynamic environments involving rational human participants, focusing on online linear programming (OLP). We explore scenarios where buyers have access to either the complete or partial transaction history and model their optimal decisions. In the first scenario, buyers face a classification problem; we discover that the buyers achieve no asymptotic information asymmetry. In the second scenario, buyers use active learning to infer hidden information through testing orders; we analyze buyers' estimation accuracy and efficiency in different market structures. By considering the buyers' information asymmetry and estimation errors, we reveal the conditions by which the market price and direction are determined. By modeling the complexities introduced by active and rational participants, we offer a new perspective on online optimization and extend traditional OLP.

32 - Inpatient Management with Proximal Policy Optimization

Qihao Wu, The University of Hong Kong, Hong Kong, Hong Kong, Yong-Hong Kuo

Efficient inpatient management is crucial for providing good quality services to patients and enhancing patient satisfaction. The main challenge of inpatient management is the imbalance between patient demands and healthcare resources. Our research aims to address such a challenge with a Proximal Policy Optimization (PPO) framework to optimize inpatient flows. Specifically, we aim to determine, when a primary inpatient ward is full, whether the inpatient unit should hold the inpatient admission until the primary inpatient ward is available or can admit this patient to a secondary inpatient ward (which is not preferred). This dilemma lies between the costs of waiting and ward mismatches. Our PPO model dynamically makes inpatient admission decisions based on the state information including patients' profiles, ward capacities, and bed availabilities. Unlike static methods, our PPO approach adapts to continuously changing conditions of the environment to improve overflow decisions. We demonstrate the efficacy of our method by simulation experiments, where the simulation model is calibrated with real-world data. The experimental results indicate that our PPO framework can identify the “just right” optimal solution by reducing waiting and overflow costs, as compared with the baseline method and a pooling policy. Our study also discusses the practical considerations for implementing PPO in real-world large-scale applications integrating electronic health records.

33 - Novel optimization algorithm for vehicle routing

Digvijay Redekar, Arizona State University, Tempe, AZ, United States, Pitu Mirchandani

The vehicle routing problem in logistics operations involves finding continuous optimal routes in a network to visit set of destinations. These routes start from the source node such as store or delivery station, visit all destinations and return to the same source at the end of the route. The primary objective of these routes is to visit destinations while minimizing travel cost, which can include expenses for gas, electricity, associate salaries, and other resources. Our research aims to develop a novel efficient and faster algorithm to find an optimal route while minimizing travel costs. The traveling salesman problem (TSP) involves finding a route in a given network such that all nodes are visited exactly once. In complex logistics networks, finding such TSP optimal route may not be feasible. Some intermediate nodes may need to be visited more than once to complete the vehicle route. Such networks are not solvable using traditional TSP algorithms. We refer to these problems as minimizing revisits TSP (MRTSP). This research proposes a novel algorithm for complex TSP and MRTSP networks to find the optimal vehicle route that visits all destinations while minimizing travel costs. Application and performance of the proposed algorithm are analyzed with different network sizes to test optimality and efficiency. Proposed novel algorithm provides similar optimal solutions with better computational time compared to traditional TSP algorithms.

34 - Variance-reduction for Variational Inequality Problems with Bregman Distance Function

Zeinab Alizadeh, University of Arizona, Tucson, AZ, United States

We address variational inequalities with a finite-sum structure, proposing a novel single-loop stochastic variance-reduced algorithm using the Bregman distance function. Our method guarantees optimal convergence for monotone settings and improves existing results for non-monotone problems with weak Minty solutions. Numerical experiments demonstrate superior performance against state-of-the-art methods

35 - Bayesian Feasibility Determination with Multiple Constraints

Tingnan Gong, Georgia Institute of Technology, Atlanta, GA, United States, Liu Di, Junying He, Seong-Hee Kim, Yao Xie

We aim to efficiently determine the feasible region with respect to constraints on a group of unknown black-box functions that map discrete alternatives to real numbers with costly evaluations. Unlike many binary classification methods that primarily focus on developing a classifier based on a fixed size of training data, we determine which alternative to sample next to achieve high accuracy on feasibility determination with a minimal number of samples. To accomplish this, we use Gaussian processes as surrogate models and introduce a novel value-of-information acquisition function for adaptive sampling under multiple constraints. We thoroughly analyze the convergence of our proposed scheme and demonstrate its effectiveness through numerical experiments.

36 - A Hybrid Crop Modeling Approach for Predicting Biomass Production of Sorghum

Yanbin Chang, Oklahoma State University, Stillwater, OK, United States, Maria Salas-Fernandez, Lizhi Wang

Accurate predictions of crop yield are important for optimal resource management, especially in areas with variable climate and resource availability. In previous studies, researchers have explored two major modeling approaches, processed-based and data-driven methods. This paper proposes a new hybrid crop model for simulating the biomass sorghum growth process and predict the final yield. The model uses a detailed descriptive sorghum growth model to represent how phenotypes are determined by genotype, environment, management, and their interactions, while employing data-driven techniques to calibrate genotypic parameters from experimental data. Results illustrate that the hybrid crop model can achieve an accurate biomass prediction with around 7% relative root-mean-square-error with both training and test data sets. This approach has the potential to enhance the accuracy and applicability of biomass sorghum growth and yield prediction models.

37 - Systematic Review on Patient Personas

Jhanille Hurde, Binghamton University, Binghamton, NY, United States

Background

The development of patient personas is crucial for enhancing healthcare services by providing detailed and accurate representations of patient groups. This systematic review aims to analyze the current methodologies and applications of patient personas in healthcare, identify gaps in existing approaches, and explore the potential integration of advanced technologies such as machine learning (ML) and artificial intelligence (AI) to improve persona creation.

Objectives

1. To analyze previous patient persona creation methodologies.
2. To identify gaps and limitations in existing patient persona creation methodologies.

Method

A comprehensive search was conducted in electronic databases including PubMed, Web of Science, and Science Direct, resulting in 1,893 articles. After removing duplicates and applying inclusion and exclusion criteria, 24 articles were selected for review. The inclusion criteria focused on peer-reviewed articles published from 2013 onwards, centered on patient or user persona creation within healthcare.

Results

The use of qualitative data, though valuable, introduces biases that can affect persona accuracy. Despite the limitations in using personas, patient personas have been effectively utilized to meet patient needs and inform healthcare design decisions. However, gaps remain in the standardization and long-term implementation of personas in clinical settings, as well as in the performance metrics used to evaluate their effectiveness.

Conclusion

This review underscores the importance of patient personas in enhancing healthcare delivery but also identifies significant gaps and limitations in current methodologies. To address these issues, future research should focus on integrating AI and ML techniques into the persona creation process.

38 - Developing All-Hazard Risk Analysis (AHRA) to incorporate resilience into installation planning

Mary Mitchell, US Army Information Technology Laboratory, Vicksburg, MS, United States, Susan Wolters, Timothy Perkins, Shelia Barnett, Matt Swanson, John Richards

During the Business Process Reengineering (BPR) for the Virtual Toolbox for Installation Mission Effectiveness (VTIME), the All-Hazards Risk Analysis (AHRA) was developed to incorporate climate resilience and risk into installation planning products. The AHRA will replace the Installation Climate Resilience Plan (ICRP) as an analytical process integrated into all installation plans, instead of just being a static plan.

39 - Using Multi-Objective Genetic Algorithm for Food Delivery Service Path Optimization Considering Safety and Mileage

Pei-Fen Kuo, National Cheng Kung University, Tainan, Taiwan, Yu-Jung Lin, Chung-Wei Shen

Recently, online food delivery services have surged in popularity due to their convenience, yet this growth has raised significant safety concerns. Delivery drivers often lack professional driving training, and the pressure for swift deliveries encourages aggressive driving behaviors, heightening crash risks. Current navigation apps prioritize shortest or fastest routes for efficiency, neglecting safety considerations. Although some academic studies have developed routes focusing on safety or minimizing air pollution, these routes often sacrifice efficiency.

This study aims to develop a method for constructing safer delivery routes within acceptable travel distances. Utilizing real online food delivery data from 486 restaurants in Daan District, Taipei City, we created artificial Origin-Destination (O-D) demands and initially computed the shortest route for each O-D pair. Each route's crash risk was assessed using real crash data, and then Yen's algorithm was employed to generate alternative routes by replacing the most dangerous road segments with safer alternatives nearby. This iterative process formed the initial population for NSGA II, a well-known multi-objective genetic algorithm.

Simulation results indicate that compared to the shortest routes, the traditionally safest routes reduced average risk by 69% but increased average mileage by 145%. Conversely, our proposed routes reduced average risk by 59% with a more modest increase in mileage by only

47%. This study proposes a method for designing safer food delivery routes that delivery platforms could implement to mitigate accidents among their workers.

40 - A Multi-layer Network Analysis Approach to Weaponized Disinformation Diffusion and its Impact on Infrastructure Systems

Alice Nanyanzi, University of Oklahoma, Oklahoma, OK, United States, Kash Barker, Sridhar Radhakrishnan

This study delves into the dynamics of multi-layer networks representing an information layer and an underlying physical infrastructure layer. We focus on processes of diffusion (i.e., the spread of information or influence) in the information layer, and we focus on the performance of the flows in the physical infrastructure layer. We investigate how diffusion within one layer impacts performance in other interconnected layers under diverse conditions. Notably, we explore the effects of increasing the number of inter-layer edges, variations in diffusion parameters, and higher network density on physical infrastructure behavior. We integrate diffusion and network optimization models to study different characteristics, including potential points of failure and importance measures for critical components in both layers, and we develop strategies to improve robustness across both layers.

41 - Semiconductor Manufacturing Process Visualization: Focusing on Resource Groups with Significant Effect on Yield

Gyeunggeun Doh, Department of Industrial Management Engineering, Pohang University of Science and Technology(POSTECH), Nam-gu, Pohang 37673, South Korea, Korea, Republic of, Minseok Song, Deoksang Lee, Jeongwoo Seo, Changho Shin

In multistage semiconductor manufacturing process, the combinations of resources across various steps significantly affect yield. We propose a two step method for process visualization, focusing on significant resource groups. Association rule analysis is applied to discover significant resource groups. Then, resource-oriented transition system is utilized to visualize the overall process, highlighted with significant resource groups, thus offering insights to yield optimization.

42 - Maxflow-Based Integrated Network Design and Scheduling (INDS) Problems with Degraded Capacities

Xiaowei Guo, Clemson University, Clemson, SC, United States, Thomas Sharkey

We consider the problem of upgrading arc capacities in a network in order to maximize the total flow in the network over a time horizon. We are interested in determining both which arcs to upgrade (network design decisions) and when to upgrade them (scheduling decisions) while also considering the fact that the capacities of arcs undergoing their upgrading process will be degraded. We introduce a novel heuristic method based on properties of the maximum flow to solve the problem on realistic networks and compare its performance to a mixed-integer programming model for the problem. The heuristic method is tested on synthetic Manhattan Grid networks and real-world networks from Eastern Massachusetts, Anaheim, and Chicago.

43 - Integrating Fragility in Joint Power and Gas Transmission Models

Eric Taylor, Pennsylvania State University, University Park, PA, United States, Seth Blumsack

The resilience of coupled natural gas and power transmission systems during severe weather conditions is vital for the functioning of today's society. This study incorporates fragility curves into a two-stage stochastic expansion planning model to assess and enhance the resilience of the coupled systems when the location and severity of extreme weather events are both uncertain. The approach builds on existing research by introducing uncertainty in component failures through the use of a fragility curve method. Fragility curves, demonstrating the relationship between different wind intensities and likelihood of component failure, simulate how the system responds to geographically correlated failures. The model was integrated on a small public-domain gas-grid test system. Unsurprisingly, the use of fragility curves in these types of planning models leads to fewer network expansions. We find that even in the worst-case contingencies the chosen network expansions do not substantially reduce unserved energy. Our work suggests a need for improved planning frameworks that can handle multiple sources of uncertainty.

44 - BCFR: Incorporating "Resilience" into "Better, Cheaper, Faster" for Supply Chain Planning

Shuting Peng, Boston University, Boston, MA, United States, Sung Bo Ma, Po-Wei Chang

The increasing frequency and severity of global supply chain disruptions have motivated the development of a decision-making framework for procurement managers aiming to incorporate resilience into supplier evaluations. The methodology combines expected value analysis, indifference probabilities, and pairwise comparisons to rank suppliers based on four key dimensions: quality (better), cost (cheaper), delivery (faster), and disruption risk (resilience). Its primary contribution lies in quantifying each dimension on the same economic scale, considering both direct impacts as well as upstream and downstream ripple effects. A user interface was developed with the following inputs for each supplier: procurement cost, non-conformance rate, late delivery prediction, and disruption probability over the planning period. The framework consists of four analysis stages; each stage uses color-coded matrices to display uncertainty and binary searches to determine indifference probabilities. First, each pair of suppliers is evaluated to determine the difference in their quality-related costs, which is added to the difference in their procurement costs. Second, each pair of suppliers is evaluated to determine the difference in their delivery-related costs, which is added to the previous results. Third, each pair of suppliers is evaluated to determine the difference in their disruption-related costs, which is added to the previous results. Fourth, the Analytic Hierarchy Process (AHP) converts all of the pairwise comparisons into a ranking of suppliers. The poster provides an example of how the best supplier is chosen among a group of globally dispersed suppliers.

45 - Topology Preserving Fitting of Trimmed NURBS CAD Model to Deformed Solids

Lijie Liu, Iowa State University, Ames, IA, United States, Adarsh Krishnamurthy, Stephen Holland, Qing Li

The shape details of manufactured components are critical for next-generation cyber manufacturing systems. However, the design intent cannot generally be linked to the as-manufactured part because of geometry mismatch. The overarching goal of this research is to establish a systematic mapping framework between as-designed models and as-built geometries (which usually deviate from the design) for applications in next-generation manufacturing systems. Our method defines mappings that make it possible to leverage the design information in the context of the as-built part, which is otherwise impossible with simple reverse engineering. Our proposed work will facilitate data mapping from different resources and modalities (e.g., dimensional metrology and nondestructive evaluation methods such as computed tomography and thermography) in manufacturing and across the product lifecycle. Hence our work will enable Manufacturing 4.0, especially digital twin systems that rely on information exchange between digital models and physical parts.

46 - Optimal Valuation of Electricity and Carbon Storage Facility for Sustainability

K Jo Min, Iowa State University, Ames, IA, United States, Samantha Bradley, Eli Sallis, Nazia Nur, Mohammad Sadat, John Jackman

Towards a sustainable world, the storage of electric power as well as of carbon has recently been playing an increasingly critical role in the areas of energy and environment. In this poster presentation, we focus on the financial viability of such facilities when the electric power and carbon prices fluctuate with significant volatility. In order to understand the financial viability, we first gather relevant price details of the electric power and carbon as well as of the storage facilities. Based on such relevant information, we next show that the fluctuations of the prices closely follow a Geometric Brownian motion process, and then explain how a stochastic optimal control problem can be formulated given such a process. The resulting second order stochastic differential equation is solved for an analytical solution, leading to a threshold price that determines the financial viability of such facility under the current price information. We then apply our model and solution to a couple of empirical cases of electric power and carbon storage facilities. The preliminary results show that the electric power storage facility seems financially justified while the carbon storage facility still needs additional public support before such facility is financially viable.

47 - Salary Insights for Data-Driven Roles

Xiahua Wei, University of Washington, Bothell School of Business, Bothell, WA, United States, Emily Nguyen

The period from 2020 to 2024 marked a critical transition in the global economy due to the COVID-19 pandemic. This era redefined corporate hiring practices, notably through the widespread adoption of remote work. Following a significant job loss in 2020, the technology sector experienced a hiring surge during 2021-2022, only to face mass layoffs and a shift towards a return-to-office policy by 2023. This led to the emergence of a hybrid work model in the post-pandemic landscape. Currently, the job market remains challenging for many job seekers.

This backdrop raises critical questions about the impact of flexible work models on employee compensation and how this impact may vary across different job characteristics. Such inquiries are particularly pertinent in data-intensive industries, which are a significant part of the economy.

This study presents an analysis of salary data for data-centric roles from 2020 to 2024, including 15,614 data points across various metrics such as job title, remote work ratio, experience level, employment type, and company size. The findings indicate that experience level and job title significantly influence salary outcomes. On average, hybrid roles offer lower salaries compared to fully remote or on-site positions. Salary offerings from large and medium-sized companies are comparable, whereas small companies tend to offer the lowest average salaries.Despite the volatile job market and numerous layoffs, the demand for data-related positions continues to rise annually, with salaries increasing correspondingly. The market is also witnessing the introduction of new job titles, particularly those specializing in artificial intelligence.

48 - A Robust Optimization Model of Using Natural Gas for Electricity Generation in Saudi Arabia

Fahad Almutairi, The george washington university, Washington DC, DC, United States

This paper reviews the existing model of replacing crude oil with natural gas for power plants in Saudi Arabia. To reduce GHG emissions, SA announced the target of the energy sources by 2030. The electricity will be generated by natural gas and renewable energy. Currently, most of the turbines rely on crude oil. In contrast, the global model for the countries that export natural gas to the markets has another approach. They supply the gas capacity for local demand and global markets parallelly. SA has not exported gas globally yet until they cover the local demand and the electricity transformation. In this work, A robust optimization model for electricity generation in SA will be conducted. The suggested model will provide the optimal time frame of replacement crude turbines with gas. Achieving CO2 reduction requires a trade off with the cost and this is the objective of the model. This paper will contribute to the literature by providing an optimal model that aims to achieve a GHG emissions reduction target with the lowest cost in a specific time interval.

49 - Closing the Gaps: Optimality of Sample Average Approximation for Data-Driven Newsvendor Problems

Shilin Yuan, Tsinghua University, Beijing, China, People's Republic of, Jiameng Lyu, Bingkun Zhou, Yuan Zhou

We study the regret performance of Sample Average Approximation (SAA) for data-driven newsvendor problems with general convex inventory costs.
In literature, the optimality of SAA has not been fully established under both α-global strong convexity and (α,β)-local strong convexity (α-strongly convex within the β-neighborhood of the optimal quantity) conditions.
This paper closes the regret gaps for both conditions by proposing several new analysis techniques.
Under the (α,β)-local strong convexity condition, we prove the optimal regret bound of $\Theta(\log T/\alpha + 1/ (\alpha\beta))$ for SAA. This upper bound result demonstrates that the regret performance of SAA is only influenced by α and not by β in the long run. This insight enhances our understanding of how local properties affect the long-term regret performance of decision-making strategies.
Under the α-global strong convexity condition, we demonstrate that the worst-case regret of any data-driven method is lower bounded by $\Omega(\log T/\alpha)$, which is the first lower bound result that matches the existing upper bound with respect to both parameter α and time horizon T. This lower bound result advances the theoretical understanding of the performance limit of data-driven methods in newsvendor problems.
Moreover, our new analysis techniques for upper bound and lower bound might be of independent interest for broader data-driven problems.

50 - Analyzing and Optimizing the Delay Resilience of HSR Network under Unforeseen Events

JIN LUO, Tongji University, shanghai, China, People's Republic of, Yuling Ye, Ziyue Zhu, Yihan Tian, Wentao Zhou, Mingchu Han

General unforeseen events impair the capacity of networks temporarily, often necessitating measures such as speed limitation or service outage to overcome these events, consequently resulting in delays of trains. Enhancing the capability of high-speed railway (HSR) network to recover from delays caused by general unforeseen events is one of the focal points in transportation organization. This article aims at addressing delays of trains that resulting from general unforeseen events in HSR network. Based on analyzing the concept of resilience, the connotation of delay resilience in HSR networks is proposed. Evaluation indicators that assess the capability of HSR network to recover from delays caused by general unforeseen events are established from the perspectives of both degree and speed of recovery. Furthermore, an optimization framework for delay resilience in HSR network through operational adjustments is explored. Firstly, a multi-objective mixed integer programming (MIP) model is developed to optimize delay resilience on the fault section. Secondly, considering delays of trans-regional trains will affect the operation of adjacent sections, an optimization model of delay resilience in adjacent sections is constructed. The optimization framework is applied in the case of a local HSR network in East China. Finally, the spatial and temporal propagation characteristics of delays in HSR network under general unforeseen events are discovered, which provides insights for future operational adjustments.

51 - Master Production Scheduling Problem with Multiple Forecast Information

pouria arsalani, University of Alabama, Tuscaloosa, AL, United States, Iman Dayarian, Youngsoo Kim

Master Production Scheduling plays a vital role in manufacturing planning and control, orchestrating production activities to meet customer demand. The solution quality of this problem can significantly influence the total cost, schedule instability, and service level of a production inventory system. In this paper, we examine MPS within a rolling-horizon framework, where forecast demand data is updated at each iteration, leading to non-stationary demand patterns. Unlike previous works in this field, which consider a single estimation point for demand, this paper takes into account several forecast estimations made at different times before the actual realization, alongside various forecasting methods. The problem is modeled using stochastic dynamic programming approaches and is solved as a scenario-based stochastic model to minimize inventory and production costs. Furthermore, we evaluate and compare various forecasting methods used by our industry partner to forecast demand, incorporating different sources of information. This analysis will provide insights into how to effectively use different forecasting methods to leverage their information.

52 - A Global Supply Chain Network Equilibrium Model Considering Entrepot Trade

Rumei JI, Tongji University & The Hong Kong Polytechnic University, Shanghai, China, People's Republic of, Xiaoning Zhang, Min Xu

The global supply chain plays a vital role in worldwide economic development, which urges careful attention to the impact of international trade friction on this interconnected system. Moreover, entrepôt trade is a mitigation strategy in response to such trade tensions. However, few papers have attempted to incorporate entrepôt trade into the analysis of how international trade friction affects the global supply chain. To bridge the research gap, this paper proposes a global supply chain network game model considering entrepôt trade to investigate the influence of international trade friction on global supply chains and the role of entrepôt trade in it. The governing equilibrium conditions of the model are formulated as a variational inequality problem. Additionally, this research performs numerical experiments with a global supply chain network of one final product requiring two components to illustrate how international trade friction impacts the global supply chain and how entrepôt trade mitigates the effect. The results show that international trade friction would lead to a decline in the direct trade between suppliers and firms in the countries engaged in this trade friction and foster entrepôt trade. While entrepôt trade could mitigate the negative effect of international trade friction, its capacity for mitigation is limited. Furthermore, international trade friction would also facilitate enterprise internalization. However, the response strategies integrating entrepôt trade, supplier diversity with in-house production also cannot absolutely counteract the adverse effect to sustain its trade volume.

53 - Federated Multiple Tensor-on-Tensor Regression for Multimodal Data under Data-Sharing Constraints

Zihan Zhang, ISyE Georgia Tech, Atlanta, GA, United States, Shancong Mou, Mostafa Reisi, Massimo Pacella, Jianjun Shi

In recent years, diversified measurements reflect the system dynamics from a more comprehensive perspective in system modeling and analysis, such as scalars, waveform signals, images, and structured point clouds. To handle such multimodal structured high-dimensional (SHD) data, combining a large amount of data from multiple sites is necessary (i) to reduce the inherent population bias from a single site and (ii) to increase the model accuracy. However, impeded by data management policies and storage costs, data could not be easily shared or directly exchanged among different sites. Instead of simplifying or facilitating the data query process, we propose a federated multiple tensor-on-tensor regression (FedMTOT) framework to train the individual system model locally using (i) its own data and (ii) data features (not data itself) from other sites. Specifically, federated computation is executed based on alternating direction method of multipliers (ADMM) to satisfy data-sharing requirements, while the individual model at each site can still benefit from feature knowledge from other sites to improve its own model accuracy. Finally, two simulations and two case studies validate the superiority of the proposed FedMTOT framework.

54 - Dynamics of Sentiment Involvement on Social Media in Emergencies: Case Studies Based on Microblog Data in China

boyu Zhu, Shanghai Maritime University, Shanghai, China, People's Republic of

This study focuses on the polarization of online public opinion and its formation mechanism in the era of social media in China, especially the role of official media and we-media opinion leaders in public opinion guidance. By using case analysis method and collecting data from Sina Weibo platform, this study analyzed the polarization characteristics of public opinion in network circles of eight hot social events at different stages of public opinion development, as well as the dynamic characteristics of Chinese social media users' emotions on hot issues, and reached a conclusion on the emotional tendency of public opinion.

55 - On the Use of Clustering-Based Pseudo-Class Labels for Out-of-Distribution Detection

Yujin Lee, Sungkyunkwan University, Suwon, Korea, Republic of, Seokho Kang

Out-of-distribution (OOD) detection is the task of identifying instances that deviate significantly from the in-distribution (ID) data on which a classifier has been trained. This is crucial in practice, especially when deploying classifiers in safety-critical applications such as medical

diagnosis and autonomous driving. OOD detection methods require a labeled training dataset, where each instance is annotated with its respective class label, to train a classifier. However, acquiring these class labels is often laborious and costly in real-world situations. Instead of manually obtaining actual class labels, we can derive clusters of semantically similar instances from an unlabeled training dataset and use them as pseudo-class labels. In this study, we investigate the effectiveness of various OOD detection methods when pseudo-class labels are used to annotate the training dataset. We compare the suitability of different clustering algorithms with varying numbers of clusters for generating pseudo-class labels, evaluating their effect on the performance of OOD detection methods. We conduct experiments using OpenOOD benchmarks.

56 - Optimal Production, Fuel Economy Investment and Credit Trading Decisions Under Dual-Credit Policy

Zhenxiao Wang, Tsinghua-Berkeley Shenzhen Institute, Tsinghua Shenzhen International Graduate School, Tsinghua University, Shenzhen, China, People's Republic of, Fen Xu, Li Xiao, Peng Yang

We study a production system that produces fuel vehicles and new energy vehicles during one selling season under the dual-credit policy (DCP), which is issued to reduce the greenhouse emissions generated from production. One specific feature of our model is that production generates two credits, either positive or negative, and DCP requires nonnegative credits at the end of the selling season and penalizes the negative credits. We show that the optimal production, fuel economy investment, and credit trading decisions depend on the initial capability of generating credits. Based on the optimal decisions, we find that DCP promotes the production of automakers who sell credits and reduces the production of automakers who purchase credits. We next discuss various factors affecting the optimal decisions and the effectiveness of DCP. In particular, a high initial capability to generate positive credits induces a \textcolor{blue}{ high profit} and large production quantity. A high credit purchasing price induces a \textcolor{blue}{low profit} and a small credit trading volume. However, the optimal fuel economy decision and the credit trading decision are non-monotone in the initial capability to generate credits, and the production quantity and the fuel economy investment are non-monotone in the credit purchasing price.

57 - Explainable AI for Risk Evaluation: Improving Projection Accuracy of Film Revenue

Doyinsolami Osobukola, The University of Tulsa, Tulsa, OK, United States, Ismail Abdulrashid

Considering the evolving landscape of the U.S. film industry, characterized by shifting consumer preferences towards streaming platforms and a projected 7.2% annual growth rate through 2030, the importance of accurate predictive analytics cannot be understated for stakeholders seeking to optimize profitability in traditional theater releases. This poster presentation employs advanced machine learning techniques including Artificial Neural Networks, Gradient Boosting, and Support Vector Machines to forecast financial risks associated with new movie releases, utilizing a dataset comprising 129 North American films released between 2016 and 2022. The results indicate that Gradient Boosting outperforms other models significantly in terms of accuracy, precision, F1 score, and area under the curve. Furthermore, the application of an explainable analytics framework, specifically Shapley Additive Explanations (SHAP), enhances the transparency and interpretability of the influence of various factors such as genre, budget, and online media promotional strategies on pre-release movie performance. This study highlights the efficacy of advanced predictive models and illustrates the potential for smarter decision-making in film production and marketing strategies, laying the groundwork for optimizing financial outcomes in the film industry.

58 - Optimal Timing for Installing a Remanufacturing and Recycling Facility Amid Sourcing Price Uncertainties and Product Lifecycle Considerations

Mohammad Ahnaf Sadat, Iowa State University, Ames, IA, United States

In this study, we investigate the strategic decision-making process for installing a joint remanufacturing and recycling facility, focusing on turbine blade production for gas turbines as a specific example. We analyze the uncertainties in sourcing costs, which include purchasing raw materials and acquiring used products from customers, treating these as dynamic stochastic variables. In contrast, the product lifecycle and the quality of acquired used products are considered dynamic and deterministic. We employ a real options analysis, specifically utilizing Monte Carlo simulation methodologies, to model and derive solutions. The objectives of this study are to determine the optimal conditions for installing such facilities, evaluate the strategic value of this flexibility, and explore how various model variables influence these decisions.

59 - Option Valuation of Energy Storage Integration: A Real Options Approach

Gazi Nazia Nur, Iowa State University, Ames, IA, United States

This poster evaluates the economic viability of integrating energy storage systems into wind energy operations, given the inherent unpredictability of wind power that often leads to mismatches between energy supply and demand. Utilizing a real options approach, we assess the financial benefit of energy storage, taking into account uncertainties in electricity demand, wind speed, and capital costs. Our focus is on the potential for energy storage to enhance the profitability of wind power through energy arbitrage and frequency control. We employ a Monte Carlo simulation and use the least square method to estimate the option value of energy storage. The goal is to determine if the additional benefits can justify the investment in energy storage, thereby providing insights into its financial feasibility within the wind energy sector.

60 - A Deep Learning Framework for High-Dimensional Time Series Forecasting

Ali Sarabi, Arizona State University, Tempe, AZ, United States, Arash Sarabi, George Runger

Accurate long-term time series forecasting remains a challenging task in various real-world applications, requiring the consideration of high-dimensional feature variables. Traditional forecasting methods often rely on manual feature selection, which can be time-consuming and subjective and may not capture the intricate relationships among variables. While advanced deep learning methods have significantly enhanced our understanding of complex data dynamics, it is important to note that time series possess distinct properties such as trend, seasonality, and autocorrelation, which differentiate them from other data sequences. These specific characteristics should be carefully taken into account in the modeling process. To address these challenges, we propose a novel architecture that combines a graph neural network block with a \ac{LSTM} encoder-decoder block for end-to-end feature learning and forecasting in multivariate time series forecasting. This architecture learns complex data relationships while considering time series properties, resulting in accurate and reliable predictions. Our evaluation of this framework on ETDataset benchmark datasets for sequence forecasting tasks shows forecasting accuracy and reliability comparable to prior state-of-the-art models. This framework helps decision-makers make informed decisions with deep learning models based on the best practices in time series analysis.

61 - Post-disaster Restoration Problem of Water Distribution Systems Under Incomplete Information

Peihong Xiao, National University of Singapore, Singapore, Singapore

Restoring water distribution systems is one of the most critical and complex tasks in post-disaster recovery. Water pipe restoration is essential for ensuring the supply of clean water to affected areas, which is crucial for relief distribution and public health. Given the limited resources, uncertainty, and urgency during disaster response, efficient and effective planning for water pipe restoration is vital to achieve connectivity between water supply and demand. In this paper, we define the stochastic water pipe restoration problem (SWPRP), which addresses post-disaster scenarios where limited information on water pipe damage is updated as restoration progresses. The primary decision in SWPRP is determining the sequence of pipes to restore in each period to maximize the benefit of satisfying water demand. To optimally solve SWPRP, we develop a partially observable Markov decision process (POMDP) model, derive several structural results, and propose a heuristic to reduce computational complexity. We compare our approach with three benchmark recovery strategies (static-importance based, damage-based, and distance-based) and test the performance on randomly generated instances reflecting various geographical and information settings. The results demonstrate the effectiveness of our method in reducing post-disaster losses.

62 - Fair and Efficient Chores Allocation via Earning Restricted Equilibria

Aniket Murhekar, University of Illinois, Urbana-Champaign, Champaign, IL, United States

We study the problem of allocating a set of indivisible chores among n agents in a fair and efficient manner. The agents have additive valuations. We consider commonly sought-after envy-based fairness notions and the efficiency notion of Pareto-optimality (PO). For the strongest relaxation of envy-freeness, namely envy-free up to any item (EFX), no better than O(n^2)-approximation is known, and achieving a constant approximation is a major open question. For the slightly weaker relaxation, namely envy-free up to one item (EF1), proving the existence of an allocation that is simultaneuously EF1 and PO allocation is another major open question; in fact the existence of \alpha-EFk and PO allocations is unknown for any constants \alpha and k! Extensive work on these problems have tackled special cases, like n=3 agents or bivalued instances, by leveraging on their special structures.

In this work, we make significant progress on both problems: for all chore allocation instances, we show the existence of (i) 5-EFX allocations, and (ii) 2-EF2 and PO allocations. Technically, these algorithms are built upon on the novel concept of earning-restricted (ER) competitive equilibrium, which limits agents' earnings from each chore. Showing the existence of an ER equilibrium turns out to be quite non-trivial, for which we derive a linear complementarity problem (LCP) formulation and show that the classic complementary pivot algorithm on the LCP terminates at an ER equilibrium. This gives the first-ever constant-factor approximation for EFX and the first non-trivial approximation for EFk+PO, that too a constant one, for constant k.

63 - A Bilevel Model to Configuring Rail-truck Intermodal Network for Dangerous Goods Shipments

Nishit Bhavsar, McMaster University, Hamilton, ON, Canada, Elkafi Hassini, Manish Verma

Rail and truck serve as the main transportation methods in North America. However, employing them as separate modes presents problems such as traffic congestion from widespread truck use and limited rail access due to infrequent rail lines. Combining these modes has the ability to overcome challenges and limitations in individual modes. As a result, intermodal rail and truck has emerged as a complement to individual modes. A key to the efficient operation of rail-truck intermodal transportation is determining associated activities such as inbound drayage, long-haul, and outbound drayage. In this research, our focus is primarily to: i) identify terminals for rail haul operation from the perspective of cost, and ii) determine routings for inbound and outbound drayage activities from the perspective of risk. To achieve this, there are a few studies that design intermodal networks as a hub and spoke system for regular freight. We extend the concept of intermodal hub and spoke networks to tactical planning of dangerous goods shipments. To this end, we develop a bilevel model in which the upper level is a *p*-hub median single allocation problem to minimise the total transportation cost and the lower level is a routing problem for intermodal shipments to minimise the total transportation risk in the network. We reduce the problem to a single level and illustrate the solution on a prototype intermodal network. We include a case study to demonstrate its application in one of the key goods movement corridors in Canada.

64 - Bayesian Distributionally Robust Optimal Investment Banking Contract Design

Ziheng Su, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Huifu Xu

hello

65 - A Tri-Mode Delivery System to Support Reliable and Efficient Last-Mile Deliveries

Minghao Chen, Columbia University, New York, NY, United States

In the rapidly evolving landscape of logistics and transportation, innovative delivery systems are becoming essential to meet the increasing demand for efficient, timely, and flexible solutions. One such cutting-edge approach is the integration of truck-drone-robot delivery systems. This hybrid model leverages the strengths of each component—trucks, drones, and robots—to create a seamless and highly efficient delivery network.

Trucks serve as the backbone of the system, providing long-haul transportation and acting as mobile distribution hubs. They carry large volumes of goods over extensive distances and can position themselves strategically within urban and suburban areas.

Drones bring agility and speed to the system, capable of bypassing traffic and reaching destinations quickly, particularly in densely populated or hard-to-reach areas. They are ideal for delivering lightweight packages over short distances, directly from the truck to the customer's location.

Robots, particularly ground-based autonomous robots, add precision and reliability to the last-mile delivery process. These robots can navigate sidewalks and streets, delivering packages right to the doorstep. They are equipped with advanced sensors and navigation systems, ensuring safe and accurate delivery even in complex urban environments.

By integrating these three components, the truck-drone-robot delivery system offers a versatile and scalable solution that enhances delivery efficiency, reduces costs, and improves customer satisfaction. This synergy of technologies represents a significant advancement in the field of logistics, paving the way for the future of urban and suburban delivery services.

66 - Modeling Electric-vehicle Infrastructure Resilience Using an Agent-based Simulation Approach

Adelyn Heuer, Wichita State University, Wichita, KS, United States, Ehsan Salari

In recent years, there has been a significant increase in the sale of electric vehicles (EV), surpassing a market share of 6% for new vehicle sales in the US. The EV transition is accelerating at a time of growing concerns for climate change. The frequency and severity of natural disasters and extreme weather events have intensified over the past decade and the trend is predicted to continue. Extreme weather events often lead to sudden spikes in charging demand and widespread power outages, potentially disrupting power supply to households and charging stations. The goal of this research is to investigate the resilience of the EV charging infrastructure in the State of Kansas.

We employ agent-based simulation modeling to characterize the uncertainty associated with the decision-making process of individual EV owners during both normal and extreme conditions and use the model to study emergent patterns in the EV charging demand and the potential strain put on the EV charging infrastructure in the State of Kansas. The simulation model emulates major Kansas highways and interstates, establishing a network of cities and DC Fast charging stations to represent potential routes and stations available for statewide transportation.

The simulation model is used to identify any deficiencies in the current EV charging infrastructure in the State of Kansas and assess the performance of resilience-building interventions, including the design and operation of fixed and mobile charging stations as well as planning public information campaigns for managing EV-charging demand during disasters.

67 - An Exact and Efficient Algorithm for Basis Pursuit Denoising via Differential Inclusions

Gabriel Provencher Langlois, New York University, New York City, NY, United States, Jerome Darbon

Basis Pursuit Denoising (BPDN) is a cornerstone of compressive sensing, statistics and machine learning. Its applicability to high-dimensional signal reconstruction, feature selection, and regression problems has motivated much research and effort to develop algorithms for performing BPDN effectively, yielding state-of-the-art algorithms via first-order optimization, coordinate descent, or homotopy methods. Recent work, however, has questioned the stability, accuracy and efficiency of these state-of-the-art algorithms for BPDN. For example, the glmnet package for BPDN, which is state-of-the-art due to its claimed efficiency, suffers from instability and can yield inaccurate solutions that lead to many so-called false discoveries. Another example is existing homotopy methods for BPDN; most require technical assumptions that may not hold in practice to compute exact solution paths. Without a stable, exact, and fast algorithm, these shortcomings will continue to hinder BPDN for high-dimensional applications. Here, I will present a novel homotopy algorithm based on differential inclusions that is stable and performs BPDN exactly (numerically, up to machine precision). We will present some numerical experiments to illustrate the efficiency of our algorithm and discuss various theoretical implications of our algorithm.

68 - Net-Zero EV Charging Infrastructure for Texas through 2040

Valentina Mora, Texas State Univerisity , San Marcos, TX, United States, Tongdan Jin

The "Sizing Renewable Microgrid for Net-Zero and Resilient EV Charging of Texas through 2040" project aims to address the pressing need for a sustainable and reliable electric vehicle (EV) charging infrastructure in Texas. With the Electric Power Research Institute (EPRI) projecting that EVs could constitute up to 55 percent of all vehicles in Texas by 2040, there is an urgent demand for a forward-looking solution. Furthermore, this growth in EV adoption presents the opportunity to significantly reduce carbon emissions if these vehicles are charged using renewable energy sources.

This project's primary objectives are to plan and design a net-zero statewide EV charging infrastructure, implement reliable and cost-effective charging stations, and integrate wind turbines and solar photovoltaic (PV) microgrid systems to ensure power resilience and zero carbon emissions. By achieving these goals, we will contribute to Texas' sustainability, reduce carbon emissions, and create a blueprint for future EV charging infrastructure development.

69 - Optimizing Policy Decisions in Interconnected Populations: A Spatially-Dependent Framework for Dynamic Decision-Making

Jimi Kim, University of Texas at Dallas, Dallas, TX, United States, Yunan Wu

Dynamic decision-making is crucial in policy formation. In reality, states or countries typically make these decisions, and their effects are interdependent due to spatial relationships. However, conventional policy decision-making strategies often overlook these spatial effects, assuming no interference among individuals. In this project, we propose a novel framework to measure these interdependent effects across multiple stages. We also propose the methods to estimate the optimal policy regime taking the spatial effects in consideration for a series of time spots, as well as constructing confidence intervals for the coefficients indexing the optimal policy regime based on multiplier Bootstrap methods. We rigorously demonstrate the validity of the proposed estimation and inference methods.

We apply the proposed method on a case study on COVID-19 school closing policies. We develop a composite outcome variable that balances public health concerns with economic activity. This outcome metric combines the Standardized Incidence Ratio (SIR) for COVID-19 cases with a mobility index, facilitating precise policy interventions by each state aimed at reducing confirmed cases without excessively restricting mobility. By applying our methodologies to real-world data on state-level interventions and outcomes, we illustrate how this approach can optimize policy decisions. Our findings have substantial implications for enhancing the effectiveness of personalized intervention strategies in interconnected populations. This approach has the potential to revolutionize precision policymaking in spatially dependent contexts while maintaining a balance between public health and economic considerations.

70 - Meta-Analytic Predictive Priors for 2 X 2 Tables with Structural Zeros

Will Stamey, University of Notre Dame, South Bend, IN, United States, James Stamey

High quality prior information can lead to better decision making by improving precision in estimation and by providing realistic estimates to power studies. This is especially critical in business and healthcare settings where trials are expensive or risky. One approach to using historical data to develop prior distributions is the meta-analytic predictive prior. We propose a hierarchical Bayesian model for the focal parameters in a 2x2 table with a structural zero. This is a commonly used model for correlated proportions such as in treatment sequences where only non-responding (or only responding) subjects are treated a second time. We investigate the performance of the hierarchical model via simulation. We then illustrate the usefulness of the model by showing how a set of historical studies can be used to build a predictive distribution for a new study that can be used as a prior distribution for both the rate ratio and marginal probability of a positive test.

71 - A Dark Side of Trust: Examining the Influence of Environmental Risk Perception on Citizens Plastic-Avoiding Behavior

Bairong Wang, Shanghai Maritime University, Shanghai, China, People's Republic of, Bin Liu, Yong Li

This study explores the influencing dynamics of environmental risk perception on plastic-avoiding behavior by incorporating government trust and environmental locus of control within the influencing structure. Via an online survey, this study received 1126 valid responses and used partial least square-based structural equation modeling (PLS-SEM) techniques for data analysis. Three major findings are obtained. First, environmental risk perception positively impacts people's plastic avoiding behavior. Second, this relationship is partially mediated by environmental locus of control. Finally, government trust moderates the impact of environmental risk perception on both the environmental locus of control and plastic-avoiding behavior. When government trust is higher (lower), environmental risk perception has less (more) influence on the environmental locus of control and plastic-avoiding behavior. Therefore, absolute high government trust is far from ideal in environmental management because it induces high government dependence, which stimulates people's "inertia" and makes them shirk their responsibilities for environmental protection. To reduce the dark side of government trust, it is suggested that the government shows some "weakness" and emphasizes its need for the public's support for plastic crisis management.

72 - Massively Parallel Environments for Large-scale Combinatorial Optimizations Using Reinforcement Learning

Deron Diaz, Rensselaer Polytechnic Institute, Troy, NY, United States, Joshua Pile, Philip Paterson, Ethan McCartney, Xiao-Yang Liu, Ming Zhu

Combinatorial Optimization (CO) problems--such as finding the MaxCut of a graph, ground state of the Ising model, or optimal circuit designs--are NP-hard, making high-quality solutions challenging due to the exponential growth of the search space. Since quantum circuit and digital circuit optimization are theoretically equivalent, finding optimal quantum circuits--a crucial problem in quantum computing--also falls into this category. Traditional methods--heuristics and evolutionary algorithms--are often inefficient. Reinforcement Learning (RL) offers a promising alternative, utilizing powerful search capabilities and GPU-accelerated training. However, CPU-based RL environments face significant sampling efficiency bottlenecks.

This study applies a GPU-based sampling method to address the scalability issues of CPU-based sampling. The parallel processing power of GPUs causes the speed for obtaining high-quality samples to increase significantly. This is crucial for large and complex graphs--like the MaxCut problem--and other NP-hard problems like quantum circuit optimization, where processing different vertices and edges in parallel is markedly faster than CPU-based methods.

The results of the study highlight an empirical speedup of three orders of magnitude in the sampling process compared to CPU-based methods. It is demonstrated that GPU-based sampling greatly enhances the efficiency of finding high-quality solutions for large CO problems. Our implementations support many parallel environments--ranging from 8,000 to 16,000--enabling a 100x speedup in the training process. Key contributions include the development of GPU-based massively parallel environments for MaxCut; and the implementation of MCMC simulations on GPUs through the use of GPU tensors for sampling to eliminate the CPU-GPU communication bottleneck.

73 - Unsupervised Promptable Defect Segmentation In Laser Additive Manufacturing

Israt Zarin Era, West Virginia University , Morgantown, WV, United States, Imtiaz Ahmed, Srinjoy Das , Zhichao Liu

In the domain of Laser Additive Manufacturing (LAM), precise image-based defect segmentation is crucial for ensuring product quality and enabling real-time process control. However, this task presents several challenges, including the absence of labels and the overhead of supervised fine-tuning of models. To address these challenges, we've devised a novel framework for image segmentation employing a state-of-the-art Vision Transformer (ViT)-based Foundation model, known as the Segment Anything Model. Foundation models are currently driving a paradigm shift in computer vision tasks for various fields including biology, astronomy, and robotics among others, leveraging user-generated prompts to enhance their performance. Our approach incorporates a novel multi-point prompt generation scheme through unsupervised clustering eliminating the need for data labels or supervised model fine-tuning. We apply this framework to porosity segmentation in a case study of laser-based powder bed fusion (PBF) and achieve high Dice Similarity Coefficients (DSC) without the requirement for supervised fine-tuning in the model.

74 - Logistics of Infrastructure Network Restoration under Incomplete Information

Subhojit Biswas, Texas A&M University, College Station, TX, United States, Bahar Cavdar, Joseph Geunes

In this paper we study repair crew routing problem for infrastructure network restoration under incomplete information. We consider a disrupted infrastructure network where the dispatchers know the locations of service losses but not necessarily the actual fault locations. We model this problem as a finite horizon Markov decision process and develop efficient solution methods using reinforcement learning methods. Our solution method uses structural results and state-space aggregation to address the time-sensitive nature of such decisions.

75 - A Graph-Theoretic Approach to Scenario Reduction for Stochastic Generation Expansion Problems

Sara Shaddel, Pennsylvania State University, State College, PA, United States, Seth Blumsack

Operations research and optimization play critical roles across numerous fields, from energy systems to financial portfolio management. In stochastic programming, the challenge of managing large sets of scenarios to represent uncertainties significantly complicates decision-making processes. This research introduces a novel graph-theoretic approach to scenario reduction aimed at streamlining these complex models, thus enhancing the robustness and efficiency of decision-making under uncertainty. We implemented this method in a electricity generation expansion planning (GEP) problem, demonstrating its effectiveness in optimizing strategic decisions in energy systems.

76 - Modeling and Design of Net-Zero EV Charging Infrastructure through 2040: A Case Study of Texas

Valentina Mora Casallas, Texas State University, San Marcos, TX, United States, Saha Joy, Arslan Abbasi, Tongdan Jin

This research project aims to address the pressing need for a sustainable and reliable electric vehicle (EV) charging infrastructure in Texas. According to the projection made by Electric Power Research Institute (EPRI), EV could constitute up to 55 percent of all vehicles in Texas by 2040. There is an urgent demand for a forward-looking solution for electric vehicle service equipment planning and deployment. Furthermore, the fast growth in EV adoption presents the opportunity to significantly reduce carbon emissions if the vehicle fleet is charged using renewable energy sources, such as wind and solar energy. This project's primary objectives are to plan and design a net-zero statewide EV charging infrastructure, implement reliable and cost-effective charging stations, and integrate wind turbines and solar photovoltaic (PV) microgrid generation to ensure power resilience and zero carbon emissions. Based on the projected EV fleet size, we use the EVI-Projection Tool to determine the statewide Level 2 and Level 3 chargers. Then, the sizing and siting of solar and wind capacity to power the entire infrastructure is obtained. By achieving these goals, we will contribute to Texas' sustainability, reduce carbon emissions, and create a blueprint for future EV charging infrastructure development.

77 - Assessing the Feasibility and Economics of Seasonal Hydrogen Storage in the Power Market

Yuheng Zhang, Peking University, Beijing, China, People's Republic of, Guannan He

Hydrogen has increasingly been an attractive energy vector in the context of carbon neutrality. With the fast development of relative technologies in the hydrogen supply chain, including generation, transportation, storage, and distribution, the hydrogen economy, of which the trade scale is estimated to be 18 EJ (LHV) in 2050 according to IRENA, is emerging in the global range. In particular, in the power system, hydrogen storage has long been considered a solution to long-term and short-term storage to balance intermittent renewable generation and uncertain demand. However, the economics of hydrogen storage have not been systematically revealed, jeopardizing the deployment of hydrogen. In this paper, we deeply dive into hydrogen's economic viability in the power markets using a general energy arbitrage optimization model. Three different market schemes including day-ahead, time-of-use, and deduced seasonal price schemes are compared with different hydrogen storage configurations. Underground caverns, gaseous tanks, and liquid hydrogen containers are considered to reveal the difference in economics for different hydrogen storage types. The results reveal that the seasonal price is appropriate for prompting hydrogen deployment, especially in long-term energy storage applications. The ratio of revenue to costs could reach about 0.8 for gas hydrogen storage and more than 1 for underground cavern and liquid hydrogen storage in our derived seasonal price scheme, meaning that these types of hydrogen storage are profitable for investors with a proper market scheme.

78 - Learning Real-Time Intention from Noisy Behavioral Data via State Space Model

jiaxuan jiang, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Jiapeng Liu, Milosz Kadzinski, xiuwu Liao

Dynamic intention recognition has been utilized across various fields, such as autonomous driving, e-commerce, human-machine interaction, and military strategy, to understand the evolving intentions. It involves analyzing the agent's behavior over time, which poses challenges in mapping behaviors to intentions, handling noisy continuous data, and interpreting intentions in real-time. To overcome these obstacles, we introduce a novel intention recognition approach using a state space model. Our method visualizes the generation process with a directed acyclic graph, providing clear insights into dependencies and transitions. We employ Kalman filtering to model the evolution of behavior and filter out noise. Additionally, we create a classification system for predicting intentions. Extensive experiments with real and synthetic datasets demonstrate our model's effectiveness, especially in handling imbalanced data and minority classes, making it a practical solution for real-time intention analysis of moving agents.

79 - Exploring Nash Equilibrium in Airline Frequency Competition through Second-Order Cone Programming and Code-Share Agreements

Wen-Fang Wang, National Tsing Hua University, Hsinchu, Taiwan, Yu-Ching Lee, Chun-Han Wang

In the contemporary aviation industry, strategically determining flight frequencies between airports is a crucial factor that impacts market share, operational costs, and the competitive dynamics among airlines. The rapidly evolving aviation market has transformed commercial relationships from mere competition to the formation of alliances and collaborations. Among these cooperative strategies, the code-sharing agreement stands out as particularly significant.

Code-sharing enables airline to sell seats on flights operated by partner airlines, thereby enhancing participation through commercial agreements. This practice is commonly used at hub airports to enhance connectivity between long-haul and high-frequency short-haul flights. Statistics reveal that over half of the airlines in U.S. market have adopted code-sharing strategies, particularly on routes near major hub airports.

Despite the widespread use of code-sharing in the airline industry, there is a notable absence of a comprehensive quantitative model that simultaneously addresses both codeshare strategies and flight frequency competition. Recognizing this gap, this study aims to develop a frequency competition model that integrates codeshare strategies within a game-theoretic framework. The model utilizes second-order cones to represent certain constraints. To determine the Nash Equilibrium for this problem, we leverage the optimality conditions of second-order cone programming to construct a KKT model that includes primal, dual, and complementary slackness constraints. The proposed model performs quantitative calculations to determine the optimal flight frequency for each route segment and offers strategic insights regarding codeshare agreements, selecting suitable partners, and profit sharing among airlines.

80 - A Nash Equilibrium Algorithm Using Rational Generating Function to Solve Congestion Games

SHAN YUN-CHEN, National Tsing Hua University, Hsinchu, Taiwan, LEE YU-CHING, WANG CHUN-HAN

Game theory finds wide application in economics, computer science, and engineering, especially in analyzing participants' competitive or cooperative strategies. While previous research has proposed various methods for different games, an effective approach to finding all Nash equilibria in integer programming (IP) games remains elusive.

In this study, we implemented a novel algorithm capable of enumerating all pure Nash equilibria on a polyhedron. Building on existing research, when the number of players is fixed, it becomes feasible to derive a generating function containing all pure Nash equilibria and enumerate all equilibrium points in polynomial time using binary search and residue techniques. Our algorithm integrates Python, SageMath, and LattE for implementation.

To demonstrate algorithm performance, we use congestion games as an example, which are IP games based on network congestion problems with applications in traffic management, network traffic control, and supply chain management. Experimental results demonstrate that our algorithm accurately and swiftly identifies all Nash equilibria, and outperforming brute-force enumeration in solving speed. This advancement not only enhances solution methodologies for Nash equilibria in congestion games but also offers effective solutions for domains like traffic management and network optimization.

81 - Fair Allocation of Indivisible Chores: Beyond Additive Costs

Li Bo, The Hong Kong Polytechnic University, Hong Kong, Hong Kong

We study the maximin share (MMS) fair allocation of m indivisible chores to n agents who have costs for completing the assigned chores. It is known that exact MMS fairness cannot be guaranteed, and so far the best-known approximation for additive cost functions is $\frac{13}{11}$ by Huang and Segal-Halevi; however, beyond additivity, very little is known. In this work, we first prove that no algorithm can ensure better than $\min\{n,\frac{\log m}{\log \log m}\}$-approximation if the cost functions are submodular. This result also shows a sharp contrast with the allocation of goods where constant approximations exist as shown by Barman and Krishnamurthy and Ghodsi et al. We then prove that for subadditive costs, there always exists an allocation that is $\min\{n,\lceil\log m\rceil\}$-approximation, and thus the approximation ratio is asymptotically tight. Due to these hardness results for general subadditive costs, we turn to study three specific subadditive costs, namely, vertex-covering, bin-packing and job-scheduling. We show that constant approximate allocations exist for all these settings.

82 - Proportional Response in Stochastic Online Exchange Economies

Chia-Ying Lin, National Tsing Hua University, Hsinchu, Taiwan, Yu-Ching Lee

Problem Definition: This study focused on periodic exchange economies, referred to as Arrow-Debreu market, where each player acts as both a seller of a divisible good and a buyer with a certain amount of money. The value of goods fluctuates stochastically over time. Each day, players bring their goods and submit bids on the goods they prefer to maximize their utilities. Goods are allocated based on the bids provided by the players, and each seller collects the bids on their goods, which becomes their budget for the next period.

Methodology: we introduce a distributed auction algorithm, termed the “lazy proportional response”. This algorithm provides a more general framework for proportional response dynamics. It allows each player to update their bids based on the contribution of each good to their utility. Additionally, the framework requires players to save a fractional amount of money for later use.

Managerial implications: The lazy proportional response algorithm addresses privacy concerns by allowing buyers to adjust their bids directly, without revealing sensitive information. Moreover, it resolves the cyclic issues associated with linear utilities, leading to convergence in everything: utility, consumption, and prices.
Additionally, our algorithm demonstrates robust performance guarantees across various scenarios, making it universally applicable to diverse environments.
Key words: exchange markets, proportional response, online, market equilibrium

83 - The Cost of Supply Chain Complexity: Quantifying the Effect of Product Variety on Profit Margin

Daniela Ruiz, Pennsylvania State University, University Park, PA, United States

What is the cost of complexity in the supply chain? When companies assemble products to order, the products can potentially be highly customized to fit a specific clients’ needs. This strategy leads to a high number of possible product configurations, adding complexity to decisions along the entire supply chain. This research focuses on how supply chain complexity affects costs and therefore profit margin. This problem is exemplified and an approach for its analysis is proposed through a research project in collaboration with senior management and directors from IBM’s storage division. Through a two-stage stochastic linear program, demand and manufacturing data are used to model different possible demand scenarios and find optimal decisions for production with product conversion and expedited manufacturing used as recourse decisions once demand becomes certain. The resulting cost and revenue are compared for different demand outcomes changing the number of products in the offering. Comparison is to be held between scenarios which offer a highly customizedproduct portfolio and ones with a higher level of standardization and fewer products.

84 - Optimizing Border Security Strategies: A Game-Theoretic Framework

Yusuf Ihsan Tokel, University at Buffalo, Buffalo, NY, United States, Jun Zhuang, Yiqi Zhao

The United States of America has been the top country for asylum seekers for decades. Although the great majority of the origin countries are still from countries in America continents, recent trends show that more people all over the world after the COVID lockdown seek their chances to seek asylum from the United States. In this work, we investigated the most recent trends using United States Customs and Border Protection (CBP) data and generated insights to grab the attention of the field professionals and the general public to this matter. There are plenty of studies to focus on the trends from Mexico or the Northern Triangle of Central American countries. Still, to the best of our knowledge, a holistic effort to investigate the trends from the countries outside of the American continent has not been put into place. With this work, we aim to fill this gap by analyzing potential routes from various origin countries to South-Central and North America, assessing the risk factors for each pathway, and modeling the interaction between unauthorized immigrants/smugglers and the government using decision and game-theoretic framework

85 - Data-driven Approach in Hub Network Design with Demand Uncertainty

Davod Hosseini, Sobey School of Business, Saint Mary's University, Halifax, NS, Canada, Fahimeh Rahimi, Borzou Rostami, Saleh Farham

This study addresses a vehicle-based hub network design problem under demand uncertainty, with primary applications in freight distribution and parcel delivery systems. The focus is on leveraging economies of scale through effective vehicle utilization for consolidated freight movement. Key aspects include selecting hub nodes, assigning demand nodes to these hubs, determining the type and number of vehicles between hubs, and managing vehicle allocation to demand nodes to minimize total costs. Considering the impact of customer demand on vehicle utilization, the study incorporates demand uncertainty into the planning phase to ensure coverage.
To tackle the inherent complexity of demand uncertainty, we employ a data-driven strategy. This approach approximates stochastic expected costs based on historical demand data, utilizing machine learning techniques such as k-nearest neighbors for improved accuracy. Our methodology ensures that the optimal solution of the data-driven approximation closely aligns with the underlying optimization problem. However, the approximation becomes challenging with an increasing number of demand points or samples. To mitigate this, we introduce a Benders decomposition approach with efficiently solvable subproblems, enhancing the tractability of the solution process. This poster highlights our innovative methods and demonstrates their effectiveness in addressing the complexities of the hub network design problem under demand uncertainty.

86 - Optimizing Procurement: An Exact Approach to Commodity Classification with Strategic Criteria

Frederik Vos, Portland State University, Portland, OR, United States, Bita Mirzaei, Katharina Olkis

In practice, different types of buyer-supplier relationships and commodities need to be classified & managed in different ways. Approaches like the Kraljic Portfolio Matrix (KPM) and other classification tools have been developed to guide managers to make the right choices. However, managers are often confronted with the limitations of qualitative analysis methods related to these tools, particularly when increasing variables and boundary conditions have to be considered when classifying different groups to manage.

In order to address this, we introduce the Generalized Capacitated Procurement Commodity Classification Problem (GCPCCP) with strategic criteria. We also revisit the traditional employment of Clustering algorithms for supplier segmentation within the KPM, highlighting alternatives that, unlike Clustering, are designed to optimize supplier categorization directly in alignment with strategic goals. This comparative study not only illuminates the unique contributions of each method, but also enhances decision making in supply chain management by presenting a more structured and quantitative analysis within the KPM framework.

Summarized, we aim to contribute to literature by introducing the GCPCCP with strategic criteria, also providing a discussion of these potential strategic criteria (such as sustainability targets, attractiveness / preferences, quality assurance criteria and interdependency constraints), focusing on their economic impact. We will also show the results of the first model approach, based on the Capacitated Facility Location problem, assuming heterogeneous facilities with a set of unique attributes. We also provide the first set of benchmark instances. These findings will be presented in a poster-form.

87 - A Decision Support System for Anesthesia Staffing Optimization

Annajirao Challa, Binghamton University (SUNY), Binghamton, NY, United States, Kyle Hayes, Wen Cao, Mohammad Khasawneh

Effective management of Operating Room (OR) schedules and anesthesia staffing is crucial for hospital efficiency and patient care. This project aims to develop a decision support system to evaluate OR case volumes and calculate staffing capacity and demand across hourly time intervals by day of the week (DOW). The study includes the staffing of Certified Registered Nurse Anesthetists (CRNAs), W2 per diems, 1099 contractors, and locum tenens. This project aims to align staffing levels with workload demands, aiding in better resource utilization and patient flow. The findings support the development of an optimized work schedule, facilitating coordination between surgical teams and anesthesia providers. This project enhances operational effectiveness and highlights the importance of data-driven decision-making in optimizing surgical services.

88 - Non-metrical Similarity-based Clustering: Minimal Clique Cover with Minimal Edge-cuts

Yuxuan Ren, Georgia Institute of Technology, Atlanta, GA, United States

This research addresses a non-metrical similarity-based clustering problem, focusing on maximizing within-cluster similarity and minimizing inter-cluster similarity. The primary objective is to ensure that nodes within the same cluster exhibit similarity above a specified threshold. The secondary objective is to minimize the number of clusters while maintaining the within-cluster similarity. The tertiary objective is to minimize the number of similar node pairs across different clusters, given that the within-cluster similarity and minimal number of clusters are achieved. The clustering problem is formulated as a compact Mixed Binary Integer Programming (MBIP) model with a minimal number of variables and constraints. Despite this, the MBIP remains complex, prompting a divide-and-conquer approach: First, the similarity matrix is transformed into an incidence matrix, indicating node similarity. This incidence matrix is further converted into a graph, and clustering is performed sequentially on connected subgraphs, as nodes in isolated subgraphs cannot form clusters. Second, we employ suboptimal or optimal solutions to the minimal clique cover problem, addressing the first two objectives as feasible heuristic solutions to the MBIP. This approach accelerates the identification of good feasible solutions. Last but not least, we identify the maximal independent set and assign distinct clusters to each point within this set, thereby reducing the number of variables and constraints in the MBIP.

89 - Customized Metamaterial Footwear Design Based on Plantar Stress and Finite Element Analysis

Ziyang Zhang, Oklahoma State University, Stillwater, OK, United States, Yu Feng, Chenang Liu

This work presents a data-driven approach for designing customized metamaterial-structured shoe soles, tailored to individual plantar pressure using generative models. By integrating machine learning with finite element analysis, this work is expected to identify the optimal design based on user-specific biomechanical data. Our approach generates metamaterial structures from plantar pressure, uses finite element analysis for stress-strain data, and maps relationships via machine learning. Based on plantar pressure input, generative model optimizes metamaterial thickness in different regions for target sole stiffness and cushioning, enhancing functionality, and reducing development time and costs.

90 - Explainable Failure Prediction of Hard Disk Drive Using SMART Data

Wei Li, Northeastern University, Boston, MA, United States, Haozhou Zhou, Srinivasan Radhakrishnan, Sagar Kamarthi

Timely hard disk drive (HDD) replacement is critical to prevent data loss and streamline maintenance operations in modern data centers. HDDs are equipped with Self-Monitoring, Analysis, and Reporting Technology (SMART) to track key performance indicators with empirically established operational thresholds. In recent years, various machine learning models have utilized SMART time series data for early HDD failure prediction. However, decision-makers need greater transparency and explainability to trust and implement these data-driven failure prediction models. Using SHAP (SHapley Additive exPlanations) analysis, we proposed a methodology for extracting explainable features from the SMART time series and visualizing the effect of these features on short-term HDD failure prediction. We trained an XGBoost model with top information-rich features and evaluated the failure detection rate and false alarm rate. We illustrated the effectiveness of the proposed approach on Backblaze data for Q1 and Q2 of 2023. The model provided a 74.7% failure detection rate with only a 0.73% false alarm rate on the test data from Q3 of 2023. The results demonstrate the potential of the proposed approach for developing an effective HDD failure prediction model with explainable features.

91 - A Pareto Improvement Bumping-Rescheduling Policy for Operating Room Scheduling

Hung Do, University of Vermont, Burlington, VT, United States, David Novak, Mitchell Tsai, Andrey Ukhov

For hospitals using shared operating rooms for scheduled and emergent cases, a bumping policy is needed to accommodate emergent cases as they arrive, but it often operates with competing objectives. The current bumping policies do not offer efficient access to capacity (i.e., Operating Rooms) as well as any mechanism for collaboration. We propose, model and analyze a bumping policy called First-In-First-Out (FIFO) Bump Policy in the context of Operating Room Scheduling that facilitates load balancing and more efficient capacity usage with pooling and offers a collaborative mechanism with positive behavioral effects to speedup service rates, resulting in Pareto improvement on the dimensions of interests: total tardiness, total expected overtime and total expected idle time. Our one-day implementation, numerical and simulation study show promising improvement of the proposed policy.

92 - Optimal Lock Maintenance of the U.S. Inland Waterway Transportation System under Uncertainty

Maryam Aghamohammadghasem, University of Arkansas, Fayetteville, AR, United States, Jose Azucena, Haitao Liao, Shengfan Zhang

The U.S. inland waterway transportation system (IWTS) is an essential part of the country's multimodal freight transportation network. In addition to seasonal droughts and floods, the operations of the IWTS may be disrupted by random malfunctions and scheduled maintenance of its critical components. Among these critical components, locks play a key role in the operation of navigable inland waterways, and lock-induced disruptions to the supply chains of related industries, such as agriculture and manufacturing, often result in significant economic losses. To assess the performance of the U.S. IWTS, we develop a PyNetLogo simulation tool to capture the movements and delays of cargoes under various operational uncertainties. Using this simulation tool, a lock repair and preventive maintenance strategy is determined via Deep Reinforcement Learning (DRL) to minimize the loss due to lock-induced disruptions. To illustrate the proposed modeling and decision-making method, the McClellan-Kerr Arkansas River Navigation System is considered in our case study, where a random policy and a first-come, first-served policy conventionally implemented in practice are also presented for comparison. The results show that the optimal strategy obtained by the proposed DRL-based approach outperforms the conventionally implemented alternatives in various aspects. Most importantly, the levels of availability of all the locks are significantly improved, enabling a more seamless cargo flow along these navigable inland waterways. For the benefit of stakeholders, our further study reveals that employing multiple full-time repair crews instead of one can further
increase the availability of the locks.

93 - Steeling Against Time

JeongUk SEO, Sungkyunkwan University, Suwon, Korea, Republic of, SEONG-HYUN SEO, DONG-JOON LIM

Concept drift (CD) refers to a situation in which the statistical properties of the target variable, which the model aims to predict, unpredictably change over time. Methods for detecting and adapting to concept drift provide insights into scenarios where model performance declines due to these unpredictable changes. We propose an adaptive framework that facilitates concept drift detection and adaptation, leveraging data and feature extraction, model management, hyperparameter adjustments, and artifact versioning. Additionally, a 'buffer period' is introduced to continue data collection after drift detection, during which various 'weights' are applied to update the model. An empirical case study from the Korean steel industry highlights the necessity of autonomous retraining strategies post-model deployment and the importance of considering these strategies during model development.

94 - A New Perspective on Carrier Collaboration: Collaborative Vehicle Utilization

Ilke Bakir, University of Groningen, Groningen, Netherlands, Sahand Asgharieh Ahari, Kees Jan Roodbergen

To reduce the environmental impact and costs associated with road transport, carriers can collaborate with each other in making deliveries to their customers, typically sharing any additional profits. Our proposed collaborative vehicle utilization framework allows participating carriers to borrow trucks from each other. The borrowed truck is picked up from the lender's depot and used to transport goods from the borrower's depot to the delivery locations based on optimal routing decisions. Although order sharing, where carriers can make deliveries on behalf of each other, is a common approach to carrier collaboration in the literature, it is rarely implemented in practice due to carriers' reluctance to share sensitive customer information. In contrast, our framework does not require such information exchange. We develop two integer programming formulations for the collaborative vehicle utilization problem and design branch-and-price algorithms to solve them. Profits are shared among participating carriers using a cooperative game theoretical approach, which is solved by a constraint generation algorithm. Thanks to short calculation times, our collaborative vehicle utilization framework can solve instance sizes that are more relevant to practical applications, and typically achieves profits within 5% of those obtained through order sharing.

95 - Multi Stage Genetic Algorithm Optimization for Scheduling Flexible Flow Lines with Sequence Dependent Setup Times

Aadithan Anbuvanan, Clemson University, Clemson, SC, United States, Mary Beth Kurz

This research aims to optimize scheduling in flexible flow lines using a multi-stage random keys genetic algorithm (RKGA). The primary objective is to minimize makespan. The study evaluates traditional and proposed RKGA methods, utilizing flexible flowline data to validate the hypothesis on how chromosome representation impacts the solution quality.

96 - Reducing LPs with Arithmetic-Based DMU Identification for Large-Scale DEA

QIANWEI ZHUANG, Osaka University, Osaka, Suita, Japan, Hiroshi Morita

Data Envelopment Analysis (DEA) evaluates the efficiency of units with multiple inputs and outputs using Linear Programming (LP) for benchmarking. However, this becomes computationally challenging with large datasets. This study introduces an algorithm that employs only arithmetic computations to quickly distinguish a large portion of efficient and inefficient Decision-Making Units (DMUs), significantly reducing the number of LPs required for large-scale DEA computations.

97 - Development of an AI Model for Predicting Drug ATC Code

TaeGyeong Woo, Chosun University, GwangJu, Korea, Republic of, Min Seop So, Kibet Duncan, YONGSU HAN, Hahyeon Kang, GEONU KIM, Jongho Shin

The systematic classification of drugs into the Anatomical Therapeutic Chemical (ATC) system is essential for managing drug information and ensuring the efficacy and safety of pharmacotherapies. This study presents a comprehensive computational approach leveraging advanced machine learning techniques to predict ATC codes for a broad spectrum of drug classes. Utilizing a rich dataset of molecular structures represented by SMILES strings, we processed these through the Extended Connectivity Fingerprints (ECFP) to capture the diverse chemical properties that correlate with specific ATC classifications. Our predictive models, centered on Graph Convolutional Networks (GCNs), were adeptly applied to these molecular fingerprints to forecast the ATC class labels across all categories: A (Alimentary tract and metabolism), B (Blood and blood forming organs), C (Cardiovascular system), D (Dermatologicals), G (Genito-urinary system and sex hormones), H (Systemic hormonal preparations, excluding sex hormones and insulins), J (Anti-infectives for systemic use), L (Antineoplastic and immunomodulating agents), M (Musculo-skeletal system), N (Nervous system), P (Antiparasitic products, insecticides and repellents), R (Respiratory system), S (Sensory organs), and V (Various). The methodology demonstrated robust predictive performance across these classes, highlighting the potential of integrating cheminformatics with deep learning to enhance the precision of drug classification. The results underscore the efficacy of computational models in managing extensive pharmaceutical data and suggest significant implications for drug discovery and personalized medicine. By addressing the classification challenges across all ATC categories, this interdisciplinary research sets a new benchmark for computational approaches in pharmacological sciences, offering a scalable solution for the rapid categorization of novel therapeutic compounds.

98 - Fall Detection Prediction on Keypoints Attention Based on Transformer Model

Hahyeon Kang, Chosun University, Gwangju, Korea, Republic of, KIBET DUNCAN, Min Seop So, GEONU KIM, YONGSU HAN, TaeGyeong Woo, Jongho Shin

In human activity recognition, precise and timely fall detection still emerges as a challenge especially for health concerns. This research introduces an innovative fall detection method centered on the speed of keypoints derived from human body postures using Mediapipe. Using video datasets, these keypoints are tracked continuously, enabling the calculation of their instantaneous speeds. The Transformer architecture, recognized for its prowess in sequence-related tasks, is employed with an attention mechanism that discerns critical speed pattern shifts indicative of falls. This attention design ensures adaptation capture of temporal relations among keypoints, accentuating significant moments that might suggest a fall event. Preliminary tests on established datasets show enhanced fall detection accuracy compared to conventional techniques. A standout feature of the model is its notable reduction in false positives, a recurring issue in many fall detection systems. By analyzing the speed changes of these keypoints, a comprehensive understanding of human movement dynamics and potential fall markers is achieved. Boasting a harmonious mix of sensitivity and specificity, this Transformer-based method holds considerable promise for diverse real-world scenarios.

99 - Social vs. Default Norm-Nudging: An Experimental Investigation

Kam Kamyar, The Ohio State University, Columbus, OH, United States

I study the impact of norm-nudging on value domain in an incentivized binary-lottery choice problem. A norm is traditionally defined as the effect of actions and opinions of others A Nudge is defined to be a factor that does not affect the intrinsic value (i.e., expected value) of a lottery, yet may still affect the choice (for instance, by altering attentions). In addition, the paper investigates the effect from the source of the Nudge given nudges from statistics prior subjects vs. from the experimenters when the choice problem is given. The results show that subjects tend to prefer following Social Nudges over expected value maximization and Default Nudges, shedding light on the importance of socially-informed norms in nudging applications and policy-making.

100 - Go Smart and Green: A Sustainable Traffic Management Framework Utilizing Vehicle Energy Consumption and Emission Patterns

Sudenaz Ozvural, Drexel University, Philadelphia, PA, United States, Liang Zhang

The increasing number of vehicles on roads has reduced mobility, increased energy consumption, and emphasized environmental concerns. Especially in congested urban areas, vehicles tend to consume more gasoline and emit higher levels of pollutants. In this research, we introduce a traffic signal control system that utilizes vehicle energy consumption and emission data. Our primary objective is to effectively balance and reduce vehicle energy consumption and emissions at signalized intersections while ensuring equitable allocation of resources (such as green time and "travel credits") among different vehicle types. Specifically, the system collects vehicle energy consumption and emission data through sensors installed on vehicles, which transfer this information to the control center as the input. The control center then outputs signal timing plans based on resource allocation algorithms. Additionally, fairness indices are established for various vehicle types (including trucks, regular vehicles, and electric vehicles). Each vehicle is allocated "travel credits" for future use. Simulation experiments have demonstrated that our proposed method can significantly reduce both energy consumption and emissions simultaneously.

101 - Improving Customer Demand Forecasts in Semiconductor Supply Chain

Aparna Komarla, Solidigm, Berkeley, CA, United States

Customer demand forecasts are critical to business planning, specifically for supply and operations related tasks. Due to the short-range of available data and varying market conditions, it is often challenging to accurately forecast demand across multiple Solid State Drive (SSD) product SKUs in Solidigm's (former Intel NAND business) supply chain. In this work, I propose a time-series based model that leverages vector similarity metrics, such as cosine-similarity, to identify patterns in customer demand historically. The goal is to learn the time periods that best predict customer behavior in the future and other patterns such as a demand shift from low to high density SSDs. This approach is best for short-range time-series data with a continuous dependent variable, such as Solidigm's supply chain which captures demand on a quarterly basis.

102 - Predicting Inflection Points in Semiconductor Industry Revenue Using Macroeconomic Indicators

Aparna Komarla, Intel, Berkeley, CA, United States

Semiconductor industry revenue is cyclical in nature but often hard to predict or forecast. Experts have often lamented that macroeconomic indicators such as the Gross Domestic Product or Consumer Purchasing Index, which speak to consumer confidence and market strength, inform semiconductor market inflections. Predicting such inflections is helpful for industry supply and demand planning. In this work, we explore a range of multivariate forecasting methods from a simple linear optimization model to LSTM neural networks for inflection predictions. Since research vendors such as Gartner, S&P or IDC document semiconductor indicators in a quarterly or monthly fashion, we run into the dimensionality curses since the features outnumber the timestamps available for prediction. We see that simple methods offer high predictive power and help improve decision making.

103 - Reduction of Process Takt Time for Wheels of Mining Trucks via Simulation

Junayed Pasha, Gannon University, Erie, PA, United States, Jayed Pasha, Francesca Nemetz, William Thompson, Konner McCurdy

The efficiency of production is greatly driven by process takt time and is considered while improving the efficiency of making a product. A recurring product of a number of manufacturers, such as the Wabtec Corporation, is wheels of mining trucks. The process takt time for wheels of mining trucks can vary by each cycle or batch. This study aims to identify the process takt time through simulation modeling and analysis. The study also determines where changes within the manufacturing process of wheels of mining trucks can be made to reduce the takt time. A simulation model of the operations area is developed to perform a simulation analysis, so that the product goes through the stations, and the time for completion at each station is found. A reduction in the process takt time is aimed through the simulation analysis, whether that is moving around areas or implementing different processes. If a wheel does not pass the testing station, its rework time is also taken into account. Based on the results of the simulation conducted within the study, some recommendations are outlined for resolving the long process takt time issue. The recommendations include hiring more personnel, performing more maintenance inspections or audits to catch breakdowns earlier along with defective parts, and upholding cleanliness on the shop floor.

104 - Traffic Flow Management of the State Street-Bayfront Parkway Intersection with Simulation Modeling and Analysis

Junayed Pasha, Gannon University, Erie, PA, United States, Jayed Pasha, Kyle Anderson, Alvaro Agullo San Juan

One of the common challenges faced by urban societies is traffic congestion at intersections, as it leads to wasted time, increased fuel consumption, and environmental pollution. The City of Erie in Pennsylvania faces significant congestion at the State Street-Bayfront Parkway intersection. To address this issue, this study aims to analyze and improve traffic flow at this intersection, in order to reduce congestion, travel time, and improve overall traffic fluidity. This study has developed a simulation model that replicates real-world traffic conditions at the State Street-Bayfront Parkway intersection. Several factors are incorporated in the model, such as traffic control strategies, queue lengths, traffic volume, etc. Both the simulation model and real-world data suggest that there is heavy traffic congestion northbound and moderate traffic congestion eastbound at the intersection. It is not feasible to adjust the traffic light times without increasing congestion on one street or the other. Therefore, it is recommended that a second left turn lane needs to be added for State Street. This reduction in traffic will allow for the red times to be decreased by 5-10 seconds for Bayfront Parkway, in turn decreasing congestion in both directions. It is expected that the recommendations from this study would help achieve more traffic fluidity at both State Street and Bayfront Parkway.

105 - Enhancing Breast Cancer Prediction Accuracy through Optimized Machine Learning Models and Feature Selection Techniques

Sadaf Tabatabaee, Binghamton University, Binghamton, NY, United States, Nikoo Ebrahimi, Jenan Maher Hammoudeh Albayari, Shuxia Lu

Breast cancer remains a critical global health issue and early detection with accurate prognosis is essential for improving patient outcomes. To address dataset imbalances, we employed advanced data balancing techniques and utilized Recursive Feature Elimination (RFE) and Principal Component Analysis (PCA) for optimal feature selection. We applied and compared several cutting-edge machine learning (ML) algorithms, including random forest, support vector machine (SVM), gradient boosting machine, and logistic regression.

Our comprehensive methodology involved a detailed analysis of the Wisconsin Breast Cancer Dataset (WBCD), consisting of 569 instances. We performed rigorous data preprocessing, including cleaning, normalization, and resampling, to ensure a balanced class distribution and high-quality data for model training. The learning curves for each ML model were thoroughly analyzed to assess their performance.

Among the evaluated models, the Support Vector Machine (SVM) demonstrated superior performance, achieving the highest accuracy and F1-score. It exhibited strong initial training accuracy and improved validation performance as more data was incorporated. Logistic Regression also performed well, ranking second in terms of accuracy and F1-score. In contrast, both Random Forest and XGBoost encountered overfitting issues, characterized by high training accuracy but significantly lower validation accuracy. This indicates poor generalization to unseen data and highlights the need for either additional data or the implementation of regularization techniques to mitigate overfitting.

106 - Activating Pro-environmental Norm: The Crucial Role of Social Media in Shaping Public Attention towards Environmental Advocacy

Yidi WANG, Communication University of China, Beijing, China, People's Republic of, Lin Wang

Social media platforms play a pivotal role in shaping both individuals' online behavior and offline civic conduct. In an era marked by unprecedented environmental challenges, environmental protection requires strong individual engagement and public practice. Hence, the successful implementation of government environmental policies is particularly reliant on social media to raise public awareness, promote ethics and social responsibility, and encourage participation. However, the mechanisms concerning social media serve as powerful conduits for disseminating environmental information remain unrevealed.
Our research focuses on the extent to which and how social media platforms can help enhance the effectiveness of government environmental policies in promoting individuals' pro-environmental behaviors. Based on the norm activation theory, this study examines the mediating role of residents' activated pro-environmental norms, as reflected by environmentally-themed movies online, in elucidating the relationship between government efforts and the residents' carbon emissions.
We utilize a unique dataset comprising social media interactions centered on how residents engage with environmentally-themed movies online, sourced from China's largest online community dedicated to cultural product sharing. We supplement information on government environmental efforts, residents' carbon emissions, and environmental pollution. The final dataset spans from 2006 to 2010 from 26 provinces in China. The findings reveal a significant reduction in residents' carbon emissions resulting from the government's environmental efforts, with 32.9% of this effect mediated through activating residents' pro-environmental norms.
Our study contributes to the theoretical underpinnings of environmental communication and policy application. Furthermore, the findings enhance the effectiveness of environmental advocacy by media organizations and government policymakers.

107 - Toward a Safer World: Improving Disaster Response by Identifying Disaster-Related Tweets with Advanced NLP Techniques

Sadaf Tabatabaee, Binghamton University, Binghamton, NY, United States, Mohammad Khasawneh

Twitter is essential for real-time crisis communication, but distinguishing literal from figurative language in tweets is challenging. This study develops a machine learning model to accurately identify disaster-related tweets using a dataset of 10,000 manually classified entries. The methodology encompasses several key steps to ensure the robustness and accuracy of the model. Extensive data cleaning to handle informal language specific to Twitter. Tokenization and padding are applied to standardize tweet lengths for model input. To address class imbalance, the Synthetic Minority Over-sampling Technique (SMOTE) is utilized. Model evaluation is conducted using stratified k-fold cross-validation, ensuring each fold maintains the same distribution of classes. Performance metrics include the confusion matrix, and Receiver Operating Characteristic (ROC) curve, providing a thorough assessment of the model's predictive capabilities. In this study, four models were utilized to improve the identification of disaster-related tweets. The baseline model is a simple neural network for text classification. The first tuned model (Model 2) implements a Recurrent Model LSTM. The second tuned model (Model 3) enhances the LSTM with GloVe embeddings. The third tuned model (Model 4) further improves this setup by incorporating GloVe embeddings with SMOTE data balancing and cross-validation with an extensive text cleaning approach. Among these models, Model 4, significantly enhances performance. This approach addresses vocabulary gaps and overfitting, providing reliable information for disaster response teams and improving the accuracy and trustworthiness of social media communications during emergencies.

108 - Heterogeneous Graph Sequence Neural Networks for Dynamic Traffic Assignment

Tong Liu, University of Illinois at Urbana-Champaign, URBANA, IL, United States, Hadi Meidani

Traffic assignment and traffic flow prediction provide critical insights for urban planning, traffic management, and the development of intelligent transportation systems. An efficient model for estimating traffic flow could provide a more detailed depiction of traffic dynamics across the urban traffic landscape. However, existing traffic prediction approaches are usually limited to locations where sensors are placed and cannot predict traffic flows beyond sensor locations. To alleviate this constraint, we seek to go beyond a framework that solely depends on traffic sensors, and exploit the relationship between traffic flow and the origin-destination (OD) travel demand, guided by the concept of dynamic user equilibrium. In such "physics-based" approach, we propose a novel framework, namely a Heterogeneous Spatio-Temporal Graph Sequence Network (HSTGSN), to estimate traffic flows under dynamic user equilibrium. In particular, HSTGSN exploits dependency between origin and destination nodes, even when it is long-range, and learns implicit vehicle route choices under different origin-destination demands. This model is based on a heterogeneous graph which consists of both the road links and OD links, which connects origins and destinations, and a spatio-temporal graph encoder-decoder that captures the spatio-temporal relationship between OD demands and flow distribution. Besides, we will show how the graph encoder-decoder is able to recover the incomplete information in the OD demand. Using extensive experimental studies on real-world networks with complete/incomplete OD demands, we demonstrate that our method can not only capture the implicit spatio-temporal relationship between link traffic flows and OD demands but also achieve accurate prediction performance and generalization capability.

109 - Does new technology complement or replace human agents? Empirical evidence from an online real estate platform in China

Yidi WANG, Communication University of China, Beijing, China, People's Republic of, Lin Wang, Zan Yang, Chong Wang

The integration of Virtual Reality (VR) technology into online housing platforms has revolutionized the real estate industry, offering innovative solutions to address information asymmetry and reduce reliance on traditional agents. Although technological advance promises to spur economic growth, there is widespread concern that it could displace workers and disrupt employment. Collaborating with a leading Chinese real estate brokerage, we analyze empirical data to investigate whether VR technology complements or replaces human agents. Our findings reveal that while VR empowers agents in temporal and spatial dimensions, there is a decline in commission earnings. Interestingly, agents with lower customer satisfaction and less experience benefit from the adoption of VR technology, leading to increased work efficiency. This highlights the changing landscape of skill requirements, where standardized hard skills such as education and certification diminish in importance, while soft skills such as customer satisfaction, initiative, and years of experience emerge as critical capabilities for agents to withstand VR substitution.

This study contributes to the literature by shedding light on the nuanced dynamics of human-computer interaction in the real estate sector, elucidating how technology both complements and threatens human roles. Additionally, it expands the discourse on VR technology's impact on real estate agents, addressing gaps in existing research on the consequences of VR implementation. Furthermore, by emphasizing the importance of soft skills in navigating the digital era, this study underscores the need for education and professional training reforms to equip human professionals with the requisite skills for future success in technology-enhanced environments.

Service Operations and Supply Chain Management

Invited Session

Service Science

Chair: Muge Yayla Kullu, University of Texas at San Antonio, San Antonio, TX, United States

1 - Sourcing Strategies under Correlated Random Yields and Competition

Arda Yenipazarli, Georgia Southern University, Statesboro, GA, United States

This paper examines the strategic sourcing and diversification decisions of firms that procure from multiple unreliable suppliers and engage in quantity-based Cournot competition in the end market. Specifically, we analyze a two-echelon supply chain where two competing firms order a critical component from two external suppliers and use it to produce and sell substitutable products in the end market. The suppliers' production processes are unreliable, with the quantity delivered relative to that ordered modeled by correlated proportional random yields following a general joint distribution. Additionally, the two suppliers differ in terms of their per-unit procurement costs and yield distributions. We explore how these asymmetries and the correlation between suppliers' yields affect the firms' equilibrium sourcing strategies. Our findings provide insights into the conditions under which firms opt for sole-sourcing versus dual-sourcing and the resulting implications for competition and risk management in the supply chain.

2 - Assessing the Impact of Brand-Level ESG Violations on Sales

M. Serkan Akturk, Clemson University, Clemson, SC, United States, yao chen, Rakesh Mallipeddi, Arvind Mahajan

Employing retail transaction data and firm-level environmental, social, governance (ESG) information, our research investigates the impact of firms' ESG violations on their operational performance. We show that ESG violations lead to decreased sales for brands. Furthermore, store location and customer demographics moderate the relationship between ESG violations and brand sales.

3 - Learning-Based Optimization of Telemedicine Appointments

Ali Dogru, University of Southern Mississippi, Hattiesburg, MS, United States, Emirhan Uzunlar, Ibrahim Capar, Ozgur Araz

As more medical practices transition to a hybrid approach, simultaneously offering virtual and in-office consultations, scheduling these appointments remains a challenge due to complex computational requirements. We propose a learning-based stochastic optimization model to improve appointment capacity planning in such clinics. Using MEPS data, we train a machine learning model that predicts whether a patient will likely prefer a virtual visit or an in-office consultation. These predictions are then fed into the stochastic optimization model that finds an appointment scheduling template that minimizes the weighted average of patient indirect and direct waiting time, physician idle time, and overtime. The model considers service time variability, patient no-shows and unpunctuality, and same-day appointment demand. We show the utility of the proposed model using operational data from a psychiatry clinic.

4 - Quality Differentiation vs. Resource Utilization: Does Product Size Matter?

Muge Yayla Kullu, University of Texas at San Antonio, San Antonio, TX, United States, Dongling Huang, Isil Koyuncu

Using a large-scale airline dataset, we investigate how customer-perceived quality and resource consumption differences of products may impact a firm's product line decisions, and how they relate to its success. We hypothesize that (1) indirect effects of quality differentiation exist through resource allocation decisions and (2) increasing resource consumptions have negative implications.

Advanced Data Analytics on Reliability and Maintenance

Invited Session

Quality, Statistics and Reliability

Chair: Vipul Bansal, University of Wisconsin Madison, Madison, WI, United States

Co-Chair: Akash Deep, Oklahoma State University, Stillwater, United States

1 - Federated Multi-Way Pca for Heterogenous Data

Madi Arabi, North Carolina State University, Raleigh, NC, United States, Xiaolei Fang

Tensor data, prevalent in multidimensional datasets, poses challenges for dimensionality reduction. Multiway Principal Component Analysis (MPCA) is a widely established method to address this by seeking projection matrices for dimensionality reduction across all modes. While traditional MPCA assumes tensors of identical dimensions, this paper extends MPCA to heterogeneous data from multiple users. A federated heterogeneous MPCA (FHPCA) framework is proposed, enabling users to maintain data privacy. FHPCA employs a collaborative Incremental Singular Value Decomposition (ISVD) approach in updating shared matrices while protecting privacy. The proposed method achieves dimensionality reduction and data privacy in heterogeneous tensor datasets, guaranteeing the same performance as traditional MPCA.

2 - Pomdp-Based Optimal Maintenance Planning Using Multiple Sensor Signals

Ahmad Salehiyan, Oklahoma State University, Stillwater, OK, United States, Akash Deep, Jaesung Lee, Minhee Kim

Effective maintenance planning is critical for optimizing system reliability. In the era of digital technologies, modern systems are equipped with multiple sensors that capture and relay information about the health of the system. However, often maintenance planning methods rely on singular data sources, such as isolated sensor readings or historical maintenance records, which may fail to provide a comprehensive understanding of equipment health and performance. This research fills this gap by proposing a framework integrating multiple sensor signals for optimal maintenance planning under partial observability. Specifically, we model the underlying degradation process as a Markov chain and relate the observable multivariate signals through a multivariate normal distribution. This modeling approach enables fusing diverse signals to estimate degradation state probabilities. We formulate the maintenance planning problem as a partially observable Markov decision process to address uncertainty from the multiple heterogeneous signals. Under certain assumptions, we prove the optimal policy possesses a control-limit structure on belief space. Extensive numerical studies and a real-world case study are used to demonstrate the approach and existence of the control limits based on cost parameters.

3 - A Scalable Approach for Condition Based Maintenance of Large K-Out-of-N Systems

Han Hu, University of Wisconsin-Madison, Madison, WI, United States, Vipul Bansal, Shiyu Zhou, Yong Chen

Condition-based maintenance(CBM) has attracted widespread attention as it can helps to reduce maintenance cost and enhance reliability of systems. For large K-out-of-N system, a common problem in CBM is that finding optimal maintenance solution is usually too computationally demanding due to the exponential explosion of state space and action space, when there is dependence between components in the system. In this work, we propose a scalable approach to find approximated solution to CBM of large-scale K-out-of-N system with economic dependence. The formulation of component-wise Markov Decision Process(CW-MDP) and adjusted component-wise Markov Decision Process(ACW-MDP) are based on extended single-component actions space and distributed single-component reward function so that component-level solutions are obtained and help to make system-level decision without using huge amount of computational resources. Convergence properties are analysed in this paper to show theoretical optimality gap. Numerical study and case study are conducted to demonstrate the effectiveness and efficiency of our approaches.

4 - Joint Model for Multi-Type Failure Event Prediction from Multi-Sensor TIME Series and Survival Data

Sina Aghaee Dabaghan Fard, Texas A&M University, College Station, TX, United States, Jaesung Lee

Modern industrial systems often have multiple components that are subject to multiple types of failure, and their conditions are monitored by multiple sensors, generating multiple timeseries signals. Additionally, time-to-failure data are commonly available. It is crucial to predict the remaining useful life (RUL) of multiple components by leveraging both multi-sensor timeseries and multi-type failure event data. In most existing models, failure mode identification and RUL prediction are performed independently, ignoring the inherent relationship between these two tasks. Some models integrate multiple failure modes classification and event prediction by using black-box machine learning approaches, which lack statistical rigor and are unable to characterize the inherent uncertainty in the system and data. In this paper, we introduce a unified approach to jointly model the multi-sensor timeseries data and RUL prediction with respect to multiple failures. We integrate a Cox proportional hazards model with a Multi-output Convolutional Gaussian Process (MCGP) in a hierarchical Bayesian framework. We employ a Dirichlet prior to account for multiple failure modes to precisely capture distinct degradation paths specific to each failure mode and accurately predict the failures within Cox proportional hazard model. Variational Bayes is used for inference, where we derive an Evidence Lower Bound (ELBO). Due to the unified framework that characterizes the associations between multiple sensor signals and multi-type failure events and their uncertainties, the proposed method outperforms existing methods.

5 - A New View of Neural Network-based Health Index: Connecting Visualization, Prediction, and Operational Decision Making

Zihan Li, University of Florida, gainesville, FL, United States, Minhee Kim

Multisensor signals are now easily accessible for remaining useful life (RUL) prediction and health state monitoring due to the quick advancement of sensor technologies. In order to optimize these signals for improved health condition assessment and RUL prediction, a variety of data fusion approaches are frequently used to generate health indices. However, most of the existing methods hardly consider the interactions between Prognostics and condition-based maintenance (CBM), which may not be effective for practitioners' asset management. To address the issue, we provide a new view of the Health Index that provides Connection Visualization between Prognostics and CBM, Prediction, and Operational Decision-Making Suggestions. In particular, a neural networks-based structure is used, and a novel loss function is developed by taking into account the variability of the generated health index at the failure time as well as its monotonicity. Once the prognostic model is trained, then we search for the best model weights that minimize the maintenance costs along “low loss curves” connecting various trained prognostic model weights. A case study on the degradation of aircraft gas turbine engines is also constructed which shows an improvement in maintenance costs of the proposed method.

1 - Synth4Seg - Learning Defect Data Synthesis for Defect Segmentation using Bi-level Optimization

Shancong Mou, Georgia Institute of Technology, Atlanta, GA, United States

Defect segmentation is crucial for quality control in advanced manufacturing, yet data scarcity poses challenges for state-of-the-art supervised deep learning. Synthetic defect data generation is a popular approach for mitigating data challenges. However, many current methods simply generate defects following a fixed set of rules, which may not directly relate to downstream task performance. This can lead to suboptimal performance and may even hinder the downstream task. To solve this problem, we leverage a novel bi-level optimization-based synthetic defect data generation framework. We use an online synthetic defect generation module grounded in the commonly-used Cut\&Paste framework, and adopt an efficient gradient-based optimization algorithm to solve the bi-level optimization problem. We achieve simultaneous training of the defect segmentation network, and learn various parameters of the data synthesis module by maximizing the validation performance of the trained defect segmentation network. Our experimental results on benchmark datasets under limited data settings show that the proposed bi-level optimization method can be used for learning the most effective locations for pasting synthetic defects thereby improving the segmentation performance by up to 18.3% when compared to pasting defects at random locations. We also demonstrate up to 2.6% performance gain by learning the importance weights for different augmentation-specific defect data sources when compared to giving equal importance to all the data sources.

2 - Outage Management in Power Distribution Networks Using Reinforcement Learning over Graphs

Jie Zhang, The University of Texas at Dallas, Richardson, TX, United States, Roshni Jacob, Steve Paul, Souma Chowdhury, Yulia Gel

Self-healing smart grids are characterized by fast-acting, intelligent control mechanisms that minimize power disruptions during outages. The corrective actions adopted during outages in power distribution networks include reconfiguration through switching control and emergency load shedding. The conventional decision-making models for outage mitigation are, however, not suitable for smart grids due to their slow response and computational inefficiency. Here, we present a new graph reinforcement learning (GRL) model for outage management in the distribution network to enhance its resilience. The distinctive characteristic of our approach is that it explicitly accounts for the underlying network topology and its variations with switching control, while also capturing the complex interdependencies between state variables (along nodes and edges) by modeling the task as a graph learning problem. Our model learns the optimal control policy for power restoration using a Capsule-based graph neural network. We validate our model on two test networks, namely the 13, 34 and 123-bus modified IEEE networks where it is shown to achieve near-optimal, real-time performance. The resilience improvement of our model in terms of loss of energy is 607.45 kWs and 596.52 kWs for 13 and 34 buses, respectively. Our model also demonstrates generalizability across a broad range of outage scenarios.

3 - Neural Operator for Accelerating Coronal Magnetic Field Computations

Bo Shen, New Jersey Institute of Technology, Newark, NJ, United States, Yutao Du, Qin Li, Haimin Wang

The application of the Tensorized Fourier Neural Operator (TFNO) to significantly enhance the computational efficiency of coronal magnetic field calculations within the Bifrost Magnetohydrodynamics (MHD) model is introduced in this study. Leveraging simulated data from the European Sunrise Science Data Center, the TFNO— an extension of the Fourier Neural Operator (FNO) that incorporates tensor decomposition for improved handling of high-dimensional data—is employed to solve time-varying partial differential equations (PDEs) over a 3D domain. The performance of the TFNO is compared with traditional machine learning methods, including Vision Transformer and CNN-RNN (encoder-decoder) architectures, to demonstrate its accuracy, computational efficiency, and scalability. A physics-analysis of the TFNO predictions is also performed to demonstrate the reliability of the method. This advancement not only accelerates the simulation of solar atmospheric phenomena but also provides more reliable prediction capabilities, thus greatly contributing to the understanding of space weather dynamics and its impact on Earth.

4 - DeepMIDE: A Multivariate Spatio-Temporal Deep Learning Model for Ultra-Scale Offshore Wind Energy Forecasting

Feng Ye, Department of Industrial & Systems Engineering, Rutgers University, Piscataway, NJ, United States, Xinxi Zhang, Michael Stein, Ahmed Aziz Ezzat

The hyper-increase in scale and capacities of modern offshore wind turbines—with altitudes approaching many of the world's tallest landmarks–motivates a departure from univariate wind energy forecasting methods that are only focused on a single representative height. In response, we propose DeepMIDE—a multivariate statistical deep learning method which—unlike existing time-series and space-time methods—jointly models the spatial, temporal, and vertical variations and dependencies in the offshore wind resource and corresponding power output. DeepMIDE is a multi-input, multi-output integro-difference equation model with a nonstationary multivariate kernel, for which key physically meaningful parameters are learnt via an advanced deep transformer architecture that extracts the governing dynamics of wind propagation and formation from streams of weather maps. Tested on real-world data from the offshore wind energy areas in the U.S. East Coast—where Giga-watt scale offshore wind farms are in-development— DeepMIDE is shown to produce forecasts that are of higher accuracy and enhanced interpretability than prevalent statistical and deep learning-based forecasting methods.

Summit - 323

Survival Analysis and Optimization Techniques

Contributed Session

Chair: Sundaravalli Narayanaswami, Indian Institute of Management, Ahmedabad, India

1 - An Overview of Survival Analysis and its Use Case in Fraud Detection

Kiruthika Sankaran, Expedia, Chicago, IL, United States

Survival analysis is a crucial statistical methodology for analyzing time-to-event data, offering insights into the probability of an event occurring over time while accounting for the complexities of real-world data. This presentation will provide a comprehensive overview of survival analysis, covering its key concepts, applications, and methodologies. We will delve into the foundational elements such as survival functions, which estimate the probability of survival beyond a certain time point, and hazard functions, which describe the instantaneous risk of the event occurring. Both parametric and non-parametric survival analysis techniques will be discussed, highlighting methods like the Kaplan-Meier estimator and Cox proportional hazards model, alongside evaluation metrics such as the log-rank test and concordance index.

Furthermore, we will explore a novel application of survival analysis in the domain of fraud detection, specifically within the context of onboarding hotels onto an online platform. The process of onboarding new hotels can be susceptible to fraudulent activities, which pose significant risks to the platform's integrity and financial health. By applying survival analysis, we aim to identify patterns and risk factors associated with fraudulent behavior. This involves segmenting the hotel data into subgroups and assessing their risk profiles over time. The analysis provides valuable insights into the timing and likelihood of fraudulent events, enabling the development of proactive strategies to mitigate fraud. Through case studies and real-world examples, we will demonstrate how survival analysis can be leveraged to enhance fraud detection mechanisms, ultimately contributing to more secure and efficient operational practices.

2 - Reducing the ChvÁTal Rank Through Binarization

Vrishabh Patil, Carnegie Mellon University, Pittsburgh, PA, United States, Gerard Cornuejols

In a classical paper, Chvátal introduced a rounding procedure for strengthening the polyhedral relaxation P of an integer program; applied recursively, the number of iterations needed to obtain the convex hull of the integer solutions in P is known as the Chvátal rank. Chvátal showed that this rank can be exponential in the input size L needed to describe P. We give a compact extended formulation of P, described by introducing binary variables, whose rank is polynomial in L.

3 - A Spatial Price Network Equilibrium Paradox

Ismael Mohammad Pour, University of Massachusetts Amherst, Amherst, MA, United States, Anna Nagurney, Ladimer Nagurney

Spatial price equilibrium models have had wide application in commodity trade in sectors such as agriculture and mineral and energy markets. Many of such models are network-based and their relevance is now heightened due to global issues such as increasing wars and crises as well as the negative impacts of climate change. Spatial price equilibrium problems are network equilibrium problems, which include traffic network equilibrium problems. We investigate whether an analogue to the Braess Paradox can occur in spatial price network equilibrium problems, which, unlike the classical Braess Paradox problem, have elastic demands, since consumers are sensitive to price. We construct a series of examples in which a spatial price network equilibrium paradox occurs in that, after the addition of a new transportation link, the demand price for the commodity rises; the supply price for the commodity decreases, and all transportation routes are now more costly. In the case of agricultural commodities such a paradox has negative implications for food security, since consumers receive a lower volume of the commodity but at a higher price. Farmers, on the other hand, also, suffer, since the supply price of the commodity decreases.

4 - Impact of a Single TIME Zone on the Indian Economy

Sundaravalli Narayanaswami, Indian Institute of Management, Ahmedabad, India

Due to the Earth’s rotation, different locations on the globe experience the day at different times. Prior to time standardisation, it was difficult to coordinate activities across vast distances. To address this problem, the globe was logically divided into longitudinal regions that shared the same time, known as a time zone. Each time zone is either ahead or behind Coordinated Standard Time (UTC), which is the primary standard adopted by the world to synchronise and regulate its time. The longitudinal extent to which one time zone is ahead of another gives us a measure for how much time difference exists between the two regions. A difference of 15 degrees longitude approximates to an hour’s difference in real time.

Given this difference in time across longitudes, many countries around the world have adopted multiple time zones within their borders to better accommodate the differences in time between its own regions. For example, Russia has 11 time zones, Australia has 3, and France has 12. There are also countries that, despite spanning thousands of kilometres, have decided to retain a single time zone, say China sets its entire nation’s time to Beijing time for the sake of national unity.

India too maintains a single time zone, set at the longitude that passes through Mirzapur in Uttar Pradesh. However, on the globe, India spans across a longitudinal range of 30 degrees from east to west. In this paper, we analyze and present the economic implications of a single timezone in India.

Summit - 324

Sustainable Practices in Fashion and Commerce

Contributed Session

1 - Combating Counterfeiting in Global Supply

Seyed Mohsen Kermani, Rotterdam Managemnet School, Rotterdam , Netherlands

This research explores the effectiveness of litigation as a strategy against counterfeiting within the fashion industry. Companies face various counterfeiting challenges, including mass counterfeiting, brand dilution, and cybersquatting. They respond by filing individual or mass lawsuits against infringers. The study examines how these legal strategies impact the influx of counterfeit goods and the market dynamics, particularly focusing on collaboration among competing firms to address mass counterfeiting.

Counterfeiters adapt their strategies based on firms' legal actions, affecting their product bundling, transport modes, and packaging decisions. This research utilizes two primary datasets: detailed records of lawsuits filed by firms from 2000 to the present, and United States Customs and Border Protection data on seized counterfeit goods. These datasets provide insights into the legal battles and frontline efforts against counterfeiting.

The effectiveness of these strategies is analyzed using econometric models and theoretical frameworks such as game theory and signaling theory. The study aims to quantify the deterrent effect of litigation on counterfeiters and its overall efficacy, offering evidence-based recommendations for firms, policymakers, and enforcement agencies to enhance anti-counterfeiting measures.

2 - Attitudinally Green, Behaviorally Not: Examining the Environment Attitude Gaps through 3D Printed Clothing Choice and Diffusion of Innovation

Lakshmi Iyer, UNC Greensboro, Greensboro, NC, United States, Wei Xie

This study leverages the Diffusion of Innovation (DoI) theory to develop a Multiple Mediated Attitudes in Environmental Protection (MMAEP) research model. The model aims to understand the discrepancy between consumers' attitudinal and behavioral commitment to environmental protection by examining the adoption of 3D printing technology-enabled clothing. Based on data collected from over 221 consumers, the analysis provides valuable insight into the apparent inconsistencies in the literature regarding environmental protection attitudes and behaviors. Empirical findings reveal that consumers' environmental attitudes do not directly influence their decisions to adopt 3D-printed clothing. Instead, these attitudes interact with and exert their effects through four constructs of Compatibility, Complexity, Trialability, and Observability from the DoI theory. The study highlights the efficacy of the DoI theory in promoting environmental protection attitudes toward adopting innovations. Moreover, it introduces 'Ease of Use' and 'Imitate Others' to effectively operationalize the constructs of less straightforward 'Complexity' and conceptually ambiguous 'Observability' within the DoI framework. The proposed model enhances the understanding of how consumers' environmental protection attitudes influence consumption behaviors in the innovation adoption process. It adds evidence to explain why consumers can be ‘attitudinally green but not behaviorally green,’ contributing to the literature on Green IS for sustainability. Through its robust methodological design and empirical evidence, this study advances the theoretical and practical understanding of how environmental attitudes influence the adoption of green technologies - 3D printing.

3 - Fashion brands' second-hand business: can it have it all?

Fan SI, National university of Singapore, Singapore, Singapore, Lucy Chen

In recent years, many fashion brands have introduced trade-in programs and started to sell second-hand products through their official websites. While recycling and reusing are environmentally beneficial, it is unclear whether introducing such recycle programs is profitable. In this paper, we build a stylized model to understand the impact of recycle programs on firms’ profitability, and find that such programs can reduce a firm’s profit. Furthermore, different payment methods to second-hand product owners can affect the firm differently.

4 - An Analytic Comparison of Three Game Theoretic Models for Waste Management Supply Chains

Nima Alizadeh Basban, State Univ. of New York, Buffalo, Buffalo, NY, United States, Nallan Suresh

Waste management firms (WMFs), a key element of circular economy, form the principal means for recycling of municipal solid waste (MSW). Operationally, both competition and collaboration processes exist among WMFs. In this paper, we develop a unique waste recycling network using three main competitive models: a Cournot competition, wholesaling competition and license competition. In Cournot competition, two WMFs independently and simultaneously collect waste and establish the price of their recycled materials during the recycling process to maximize profits. In wholesaling competition, one WMF procures recyclable waste from its competitor while vying for dominance within the same market. Lastly, in license competition, a cooperative relationship is forged through a licensing arrangement between two rival WMFs. Differentiation in prices and proportions of waste sorted/composted in each model is calculated via Stackelberg game methodology and a comparison between all defined models is made to indicate conditions for maximal recycling and profitability.

Stochastic Models and Networks

Contributed Session

Chair: Aditya Gopalan, UIUC, Urbana, IL, United States

1 - Scaling Limit of a Stochastic Hegselmann-Krause Model

Aditya Gopalan, University of Illinois Urbana-Champaign, Urbana, IL, United States, Partha Dey, Rasoul Etesami

We consider an infinite-dimensional stochastic Hegselmann-Krause model on the real line. In discrete time, each point of a unit-intensity simple point process independently moves halfway toward either of its left or right neighbors, chosen uniformly at random. Co-located points are merged into a single point, and the resulting simple point process is re-scaled to unit intensity. We show that when the point processes are shifted such that there is a point at the origin, there is a unique weak limit of these dynamics when the initial point process is renewal. Using a time-reversal argument, we construct a random positive measure M on R for a dual problem, and the limiting gap between the first two points is the total mass of M assigned to R. Finally, we discuss some ongoing research directions. Joint work with Partha Dey and Rasoul Etesami.

2 - Synthesis of Conditional Probability Distributions via Eigenvalue Optimization

Brent Austgen, Sandia National Laboratories, Lowell, IN, United States, John Hasenbein, Erhan Kutanoglu

In applications involving epistemic uncertainty, often only marginal probability distributions are known for populations that are presumed to have heterogeneous subpopulations. We propose a framework for synthesizing coherent conditional distributions for a set of n subpopulations under such circumstances. The core of this framework is an optimization model defined on the manifold of stochastic matrices. Geometrically, the model is akin to identifying a maximum-volume $(n-1)$-dimensional simplex that has a given barycenter and is enclosed by the $(n-1)$-dimensional standard simplex. Maximizing the volume of a simplex is equivalent to maximizing the determinant of the $n \times n$ matrix consisting of its vertices. In our model, we employ trace maximization as a linear alternative to determinant maximization. We identify the analytical form of a solution to this model, prove it is an optimum, and present necessary and sufficient conditions for it to be the unique optimum. Additionally, we show the identified optimal solution is an inverse M-matrix with its eigenvalues on the main diagonal. We apply our framework to marginal distributions of generator outages and derates estimated using data provided by ERCOT after Winter Storm Uri (2021) and demonstrate how effectively the framework is able to impose heterogeneity in the stochastic behavior of generator subpopulations.

3 - A Modified Integer L-Shaped Method for Two-Stage Stochastic Programs

Benjamin Riley, University of Minnesota, Minneapolis, MN, United States, Prodromos Daoutidis, Qi Zhang

Two-stage stochastic programs often require many scenarios, and therefore many variables and constraints, to accurately model random parameters. As a result, tailored solution algorithms that exploit the model structure are often necessary to efficiently solve problems of industrially relevant sizes.

In this work, we consider two-stage stochastic mixed-integer linear programs with relatively complete recourse and binary state variables (i.e., binary first-stage decisions that affect the second stage), which are often solved using the integer L-shaped method. A typical implementation of the algorithm for two-stage stochastic programs operates by iteratively generating optimality cuts from solutions of LP subproblems and MILP subproblems (“integer subproblems”). One drawback of the classical integer L-shaped method is that optimality cuts generated by solving integer subproblems require solving the subproblems to full optimality. This can slow the solution of problems significantly and mitigate the advantage provided by parallelization in the algorithm.

In this work, we propose a modification to the integer L-shaped method that incorporates the use of suboptimal solutions to integer subproblems while still guaranteeing convergence to an optimal solution. A multicut implementation of the algorithm is tested in two case studies. In the first case study, a two-stage stochastic program is solved to determine the optimal investment into, and relocation of, mobile production modules given uncertain time-varying demands in a supply chain. In the second case study, a two-stage stochastic program is used to determine the optimal design and scheduling of renewables-based fuels and power production networks with uncertain renewable power generation.

4 - Nonlinear cut-sharing in stochastic dual dynamic programming for log-linear autoregressive uncertainty in the right-hand side

Christian Füllner, Karlsruhe Institute of Technology, Karlsruhe, Germany, Steffen Rebennack

We consider the generation of cuts in stochastic dual dynamic programming (SDDP) for multistage stochastic linear programming problems with stagewise dependent uncertainty in the right-hand side described by a nonlinear autoregressive process. We first derive cut formulas for the general nonlinear autoregressive process. For these general cuts, the computational tractability becomes a major challenge for SDDP-type algorithms. We are, however, able to develop closed-form cut formulas for the special case of log-linear autoregressive processes. The obtained cuts are in general non-convex in the history of the stochastic process, and thus can be used to tightly approximate the occurring nonconvex value functions. As the cuts are still linear in all decision variables, they can be directly incorporated into the subproblems in SDDP without compromising their linearity. If solvers do not allow for this, our formulas can be used to adapt the intercept of a given cut to a scenario at hand in a computationally tractable way. In this sense, cuts generated for one specific scenario are shared with other scenarios. Our findings are supported by illustrative examples and by a computational study of a hydrothermal scheduling problem.

Optimizing Restaurant Industry Operations

Contributed Session

Chair: Xiahua Wei, University of Washington, Bothell School of Business, Bothell, WA, United States

1 - Digital Consumption and Self Control

Zheng Wu, Purdue University, West Lafayette, IN, United States, Jiong Sun

The harmful effects of digital over-consumption become increasingly severe. The goal of our research is to analytically examine how consumers exercise self-control and how firms’ pricing schemes (subscription versus pay-per-use) and product design strategies affect their profit, consumer surplus, and consumers’ long-term health. Our findings indicate that firms’ pricing schemes and their impact on consumers’ long-term well-being are dependent on consumer characteristics and the nature of product category being consumed.

2 - Optimizing Operations in the Restaurant Industry: Evaluating the Effects of Transitioning from Tipping to Profit-Sharing

Yi Liu, University of South Dakota, Vermillion, SD, United States, Punya Chatterjee

This paper examines the impact of replacing tipping with a profit-sharing model for servers in a restaurant using an M/M/1 model. The results indicate several advantages, including improved service capacity, increased profit for the business owner, and higher income for servers. Notably, the study reveals that under certain conditions, menu prices without tipping can be lower than in the traditional tipping model, resulting in a greater customer surplus. These findings offer valuable insights into alternative pricing strategies in the restaurant industry, empowering business owners to optimize their operations for better financial performance and customer satisfaction

3 - From Scrolling to Dining: Effects of Instagram Posts on Bib Gourmand Restaurant Visitation through the Lens of ELM

Yun-An Yeh, National Cheng Kung University, Tainan, Taiwan, You-Hung Lin, Shih-Shuo Yeh, Hsin-Hsin Chang

Abstract

In the era of digital communication, social media such as Instagram have emerged as powerful platforms for restaurants to showcase their offerings and attract potential diners. Thus, understanding how users process dining information on these platforms has become imperative. This study employs the Elaboration Likelihood Model (ELM) as a theoretical framework to investigate the influence of Instagram posts on viewers' intentions to visit restaurants, with the target of Bib Gourmand restaurants. The research proposes two central route variables: Information Congruency and Information Comprehensiveness, and two peripheral route variables: Photo Presentation and Brand Identification. A total of eight scenarios are designed to represent various combinations of these variables in Instagram posts. Participants are randomly assigned into one of the eight Instagram posts of a Bib Gourmand restaurant, and are asked to complete a questionnaire assessing perceived informativeness, persuasiveness, attractiveness, and perceived restaurant image. The present study comprises seven hypotheses, all of which will be analyzed using PLS-SEM, elucidating the corresponding research findings. In light of the power of Instagram in user-generated content (UGC), the current study serves to provide a better understanding of how different characteristics of Instagram posts shape users' attitudes toward restaurants in Web 2.0 social commerce.

Keywords: Elaboration Likelihood Model; Instagram Usage; User-Generated-Content; Bib Gourmand restaurants

4 - Exploring the Relationship between Social Media Engagement and Stock Prices: Insights from Reddit

William Uyeta, University of Washington Bothell, Bothell, WA, United States, Xiahua Wei

As digital platforms increasingly influence financial markets, the role of social media engagement in shaping stock performance has gained growing attention. This study investigates the link between social media activity and stock prices, focusing on Reddit, a prominent platform for individual investors to share opinions. Analyzing daily data on the most frequently discussed stocks on Reddit, we examine how discussion volume and sentiment of investors drive stock price movements. Our findings reveal that both discussion volume and positive sentiment are significantly associated with rising stock prices. These results provide insights for investors and financial analysts, highlighting the value of monitoring social media trends to inform investment strategies.

On Security and Rescue Operations

Contributed Session

Chair: Norio Hibiki, Keio University, 3-14-1 Hiyoshi, Kohoku-Ku, Yokohama, 2238522, Japan

1 - Spatio-Temporal Analysis for Fleet Tracking and Prediction Using Indicator Kriging

Esther Jose, University at Buffalo, Buffalo, NY, United States, Moises Sudit, Rajan Batta

In maritime operations, the tracking and prediction of fleet movements are paramount for various applications ranging from navigation safety to security measures. Assuming that vessels in a fleet are spatially and temporally autocorrelated, we fit different spatio-temporal covariance models to observed fleet movements. In our experiments, the separable covariance model and the simple sum metric covariance model are found to be the best fit with respect to the mean squared error. Subsequently, spatio-temporal indicator kriging is utilized to generate probability heatmaps that estimate the likelihood of finding a vessel from the fleet in a certain location based only on the current positions of other vessels in the fleet and/or the vessels' previously observed positions. This methodology can enhance fleet-tracking in scenarios where tracking data is sparse or lost, facilitating increased situational awareness. An MIP is used to determine which ships from different fleets to locate at specific times, considering resource constraints and budget limitations. The objective is to maximize the accuracy of the generated heatmaps for each fleet.

2 - Synergistic Path Planning Considering Shipborne Uavs for Maritime Emergency Search and Rescue

Min Wang, Harbin Engineering University, Harbin, China, People's Republic of, Yuzhen Hu

Traditionally, maritime emergency search and rescue (MESAR) missions are carried out by ships, which is not cost-effective and efficiency. In recent years, Unmanned Aerial Vehicles (UAVs) equipped with search sensors or relief supplies are becoming a research focus. However, short endurance of UAVs limits their ability to conduct large-scale missions. Using a ship as a mobile supply base of UAVs can make MESAR cheaper, faster and broaden its coverage. Therefore, this paper investigates the synergistic path planning problem of shipborne UAVs for MESAR. We introduce an exact approach based on branch and bound to obtain the best sequence and clustering of the SAR locations. Each cluster will be visited by a ship and a fixed UAV group, whose launch and retrieving locations will be evaluated by a second-order cone programming. We also propose several heuristics to improve solving efficiency based on the programming. Moreover, our approaches are flexible to accommodate various constraints and objective functions of the second-order cone programming. Computational results demonstrate that our proposed solution approaches can find a satisfactory synergistic path of shipborne UAV within a feasible time.

Additionally, shipborne UAV mode significantly outperforms using ships or UAVs separately to search for people injured or transport relief supplies. Deep insights are also obtained by studying the influence of some parameters on the final solution.

3 - FURIOUS: Fully Unified Risk-assessment with Interactive Operational User System for vessels

Yooyeun Kim, Seoul National University, Seoul, Korea, Republic of, Jeehong Kim, Hyunwoo Park

Over recent years, marine collision risk assessment has advanced, enhancing maritime safety. However, existing studies often describe ship domains and collision risk assessments in a static manner, lacking interactivity. Notably, interactive visualization of collision risk in multi-ship encounter scenarios has not been sufficiently developed. This gap prompted the development of "FURIOUS: Fully Unified Risk-assessment with Interactive Operational User System for vessels." This tool aids in visualizing and analyzing collision risk of multi-ship encounter situation through real-time visualization.

Our system processes Automatic Identification System (AIS) data. The backend, implemented with Python Flask, serves data to the frontend built with Next.js and TypeScript, allowing users to specify parameters such as timeframe and distance for precise navigation planning and proactive collision avoidance. Key functionalities include ship domain calculations and collision risk assessments, supported by modules for data conversion, linear interpolation of vessel lengths, and geospatial computations.

The system supports user tasks like displaying vessels, checking ship domains, and calculating collision risks. Its interactive elements and dynamic maps facilitate real-time decision-making, ensuring navigation safety. Users can interactively adjust parameters such as ship type, time window of focus, and ship IDs, enabling tailored analyses and proactive collision avoidance. Additionally, the system contributes to novice users' understanding of complicated maritime dynamics, fostering innovation in maritime operations.

Our paper details the design, implementation, and evaluation of this tool, emphasizing its potential to transform maritime decision-making by improving situational awareness, promoting navigational safety, and enhancing operational efficiency for a safer and more sustainable future.

4 - Generalized Neural Network Assisted Gnss for Precise Attitude Estimation with Carrier Phase Ambiguity Resolution

Raul deCelis, Rey Juan Carlos University, Madrid, Spain

Determining aircraft rotation requires expressing vectors in various reference frames, typically the body-fixed and earth inertial triad. Traditionally, a matrix derived from Global Navigation Satellite Systems (GNSS) sensors, utilizing a minimum of three of them, is utilized for this purpose, relying on carrier phase difference signals. However, numerous challenges such as multiple interference sources and noise can hinder the precise resolution of integer ambiguities linked with carrier phase difference calculations. To tackle these challenges, a new approach employing neural networks has emerged, effectively handling large datasets and enhancing reliability for resolving ambiguities in carrier phase. By leveraging disparities in pseudo-range and carrier phase data, training diverse neural network architectures can resolve ambiguities and accurately ascertain the orientation of GNSS sensor matrices. This methodology can be implemented either independently or in conjunction with additional attitude sensors like gyroscopic data, resulting in significantly improved overall accuracy.

5 - Impact of the Hybrid Lump Sum Plan on Longevity Risk and Claiming Age of Public Pension

Norio Hibiki, Keio University, Yokohama, Japan, Dai Izawa

Recently, managing longevity risk is a very important issue for households approaching retirement. While deferred benefits can hedge longevity risk, few people implement deferred benefits in practice. A new plan to encourage deferred benefits, called Lump Sum, has also been studied. Maurer et al.(2018) stated that the Lump Sum plan would increase the number of deferred beneficiaries. Although the Lump Sum plan incentivizes delayed claiming, it carries a larger longevity risk than the current delayed benefits (Status Quo). In this paper, we propose a Hybrid Lump Sum plan that achieves three goals: incentivizing delayed claim, mitigating the longevity risk and other disadvantages of the old-age pension system for active workers compared to the Lump Sum plan, and eliminating the non-claiming age. In this plan, the increase in the pension due to deferred benefits is divided into annuities and a lump-sum payment. Thus, this plan is a hybrid of the Lump Sum and the Status Quo. We build a household model to evaluate the longevity risk in the Hybrid Lump Sum plan, and show its effectiveness through simulation analysis. We conduct an original questionnaire survey to examine whether the beneficiaries have the incentive to delay claiming age under the Hybrid Lump Sum plan, and we employ a logistic regression model to analyze the features of deferred beneficiaries under each plan. Moreover, we analyze the overall longevity risk of the Hybrid Lump Sum plan and the Lump Sum plan and clarify the effectiveness by using the results obtained from the questionnaire survey.

Data-Driven Mechanisms and Allocation Algorithms

Invited Session

Auctions and Market Design

Chair: Andres Cristi, EPFL, Lausanne, Switzerland

1 - Online Mechanism Design with Predictions

Cherlin Zhu, Columbia University, New York, NY, United States, Eric Balkanski, Vasilis Gkatzelis, Xizhi Tan

Aiming to overcome some of the limitations of worst-case analysis, the recently proposed framework of ``algorithms with predictions" allows algorithms to be augmented with a (possibly erroneous) prediction can be used as a guide. The goal is to obtain improved guarantees when the prediction is correct, called \emph{consistency}, while simultaneously guaranteeing worst-case bounds for arbitrarily wrong predictions, called \emph{robustness}. The majority of the work on this framework has focused on analysis of online algorithms augmented with predictions regarding the future input. A subsequent line of work has successfully adapted this framework to mechanism design, where the prediction is regarding the private information of strategic agents. In this paper, we initiate the study of online mechanism design with predictions, which combines the challenges of online algorithms with predictions and mechanism design with predictions.

We consider the well-studied problem of designing a revenue-maximizing auction to sell one item to strategic bidders arriving and departing over time, each with a private value for the item. We study the learning-augmented version where the auction designer is given a prediction regarding the maximum value over all agents. Our main result is a strategyproof mechanism whose revenue guarantees are α-consistent with respect to the highest value and $(1-\alpha^2)/4$-robust with respect to the second-highest value, for $\alpha\in[0,1]$. We show that this trade-off is optimal within a broad family of auctions, meaning that any α-consistent mechanism in that family has robustness at most $(1-\alpha^2)/4$. Finally, we extend our mechanism to obtain expected revenue proportional to the prediction quality.

2 - Stateful Posted Pricing with Vanishing Regret via Dynamic Deterministic Markov Decision Processes

Yangguang Shi, School of Computer Science and Technology, Shandong University, Qingdao, Shandong Province, China, People's Republic of, Yuval Emek, Ron Lavi, Rad Niazadeh

An online problem called dynamic resource allocation with capacity constraints (DRACC) is introduced and studied in the realm of posted price mechanisms. This problem subsumes several applications of stateful pricing, including but not limited to posted prices for online job scheduling and matching over a dynamic bipartite graph. Because existing online learning techniques do not yield vanishing regret for this problem, we develop a novel online learning framework over deterministic Markov decision processes with dynamic state transition and reward functions. Following that, we prove, based on a reduction to the well-studied problem of online learning with switching costs, that if the Markov decision process admits a chasing oracle (i.e., an oracle that simulates any given policy from any initial state with bounded loss), then the online learning problem can be solved with vanishing regret. Our results for the DRACC problem and its applications are then obtained by devising (randomized and deterministic) chasing oracles that exploit the particular structure of these problems.

3 - An Algorithm for the Assignment Game Beyond Additive Valuations

Christopher En, Columbia University, New York, NY, United States, Eric Balkanski, Yuri Faenza

The assignment game, introduced by Shapley and Shubik, is a classic model for two-sided matching markets between buyers and sellers. In the original assignment game, it is assumed that payments lead to transferable utility and that buyers have unit-demand valuations for the items being sold. Two important, and mostly independent, lines of work have studied more general settings with imperfectly transferable utility and gross substitutes valuations. Multiple efficient algorithms have been proposed for computing a competitive equilibrium, the standard solution concept in assignment games, in these two settings. Our main result is an efficient algorithm for computing competitive equilibria in a setting with imperfectly transferable utility and gross substitutes valuations. Our algorithm combines augmenting path techniques from maximum matching and algorithms for matroid intersection. We also show that, in a mild generalization of our model, computing a competitive equilibrium is NP-hard.

4 - Prophet Inequalities Require Only a Constant Number of Samples

Andres Cristi, Center for Mathematical Modeling, Universidad de Chile, Santiago, Chile, Bruno Ziliotto

In a prophet inequality problem, n independent random variables are presented to a gambler one by one. The gambler decides when to stop the sequence and obtains the most recent value as a reward. We evaluate a stopping rule by the worst-case ratio between its expected reward and the expectation of the maximum variable. Because of its connections with resource allocation and posted-price mechanisms, this problem has been intensively studied, and several variants have been introduced. While most of the literature assumes that distributions are known to the gambler, recent work has considered the question of what is achievable when the gambler has access only to a few samples per distribution. We provide a unified proof that for all three major variants of the single-selection problem, a constant number of samples (independent of n) for each distribution is good enough to approximate the optimal ratios. Prior to our work, this was known to be the case only in the i.i.d. variant.

Previous works relied on explicitly constructing sample-based algorithms that match the best possible ratio. Remarkably, the optimal ratios for the prophet-secretary and the free-order variants with full information are still unknown. Consequently, our result requires a significantly different approach than for the classic problem and the i.i.d. variant, where the optimal ratios and the algorithms that achieve them are known. We complement our result showing that our algorithms can be implemented in polynomial time.

5 - Competition between learn-and-earn pricing algorithms: A numerical study

Omer Saritac, London Business School, London, United Kingdom, Ali Aouad, Arnoud V. den Boer

Understanding how competitive dynamics between pricing algorithms affect social welfare is important for the design of online marketplaces. Recent empirical evidence and simulation-based studies suggest that advanced pricing technologies can be more likely to converge to supra-competitive prices in equilibrium.

In this work, we study the relationship between design properties of learn-and-earn algorithms and resulting market outcomes. We focus on a simple model of duopoly pricing with linear demand and cross-price substitution. We capture the differences in firms' pricing technology across three dimensions: (i) memory—volume of historical data---(ii) reactivity---frequency of price updates---and (iii) exploration---frequency of random price experiments. In synthetic numerical experiments, we find that insufficient exploration or asymmetric price technology lead to supra-competitive prices and lower social welfare. These findings support a potential new mechanism to explain market inefficiencies, caused by failure to estimate true demand under asymmetric technology.

Innovative Strategies for Vaccine Distribution and Disease Management

Contributed Session

Chair: Zeynep Ertem, State University of New York- Binghamton, Vestal, NY, United States

1 - Insights into Antibiotic Resistance Pathways: A System Dynamics Approach

Avi Roy Chowdhury, Indian Institute of Technology Bombay, Mumbai, India, Jayendran Venkateswaran, Om Damani, Manoj Kumar Das

Antibiotic resistance is expected to be one of the major threats to human health in decades to come. It is evident that the emergence of antibiotic resistance is not a one-dimensional problem but still, we don't have a clear picture of its emergence. In this study, we use the system dynamics methodology to understand the emergence pathways and identify the critical pathways to explore them more. We exercised "Group Model Building" where experts from different domains gathered and discussed their concerns/beliefs. Based on their narration and works in literature, we developed a Causal Loop Diagram (CLD) model. The CLD model identifies how free access to AB and excessive AB use lead to ABR also AB use in food production causes the emergence of ABR. We built a Stock Flow Diagram (SFD) model to simulate different scenarios to further our understanding, enabling the evaluation of intervention strategies. In the SFD model, we consider the dynamics between the bacterial population and immunity and add antibiotics as an intervention method. An external influx is considered to account for the externally contaminated environment. To investigate the emergence of ABR, we further divide the bacterial population into sensitive and resistant bacterial populations and observe the effects of AB use. Also, we investigate the consequences of the duration of AB drug administration in the case of the emergence of ABR as well as in the bacterial population.

2 - An Analytical Assessment of the Effect of African-Produced Vaccines on the Gavi Vaccine Market

Ruben Proano, Rochester Institute of Technology, Rochester, NY, United States

The COVID-19 pandemic has highlighted significant disparities in vaccine access for low-income African countries. In 2021, the African Union initiated an effort to establish vaccine manufacturing capacity in Africa to meet 60% of the continent's demand by 2040. Despite Africa being the largest vaccine market by volume, it currently produces less than 1% of its demand domestically, and approximately 80% of vaccines purchased for Africa are bought with financial assistance, mainly from Gavi. Gavi and UNICEF have established an affordable vaccine market for low-income countries that takes advantage of economies of scale, pooled procurement, coordinated tenders, and innovative financial mechanisms.

This study assesses the impact of various African vaccine manufacturing capacity levels on the UNICEF/GAVI market. It analyzes the optimal decisions of profit-driven manufacturers who must decide how to meet Gavi vaccine demand with production made within and outside the African region. The study uses Monte Carlo simulation to evaluate a two-stage stochastic optimization model, where manufacturers determine production levels within and outside Africa considering pre-determined production levels and random demands.

The results indicate that achieving the African Union's 2040 goal and incentivizing manufacturers to maintain their production capacity would result in an additional cost between 2.7 and 11.9% of the annual GAVI/UNICEF vaccine procurement budget, which ratifies the benefits of having a self-sufficient vaccine market in Africa.

3 - A Data-Driven Compartmental Stochastic Programming Model for Optimal Resource Allocation during Disease Outbreaks

Sandra Eksioglu, University of Arkansas, Fayetteville, AR, United States, Hieu Bui, Ruben Proano, Haoming Shen

During disease outbreaks and other health emergencies, effective allocation of critical healthcare resources is crucial. This is particularly relevant in rural and marginalized communities, where variability in individuals' attitudes toward embracing disease prevention procedures and uncertainty in resource availability are prevalent. For example, vaccine hesitancy (VH), defined as reluctance and refusal to vaccinate, complicates the prediction of disease spread and affects the allocation of resources. In addition, the way resources are prioritized and allocated can influence these uncertainties, which pose challenges to public health planning. To address these challenges, we propose a compartmental stochastic programming (C-MSP) model that adaptively manages healthcare resources under uncertainty. Our model integrates epidemiological and logistical considerations, capturing the dynamic and interdependent nature of disease spread and resource allocation. We developed a case study using real-life data about COVID-19 vaccination uptake from January to May 2021 and data about healthcare resources in Arkansas, U.S. Using our numerical analysis, we highlight the impact of delaying the deployment of critical resources to public health; the impact of the initial stockpile and the flexibility in increasing the supply of critical resources to public health; and the price of ensuring equitable allocation of resources over time and space. Our approach aims to provide a robust framework for policymakers, especially in resource-limited rural areas, facilitating more informed and responsive decision making.

4 - Advanced machine learning techniques for epidemic disease modeling

Zeynep Ertem, State University of New York- Binghamton, Binghamton, NY, United States

The COVID-19 pandemic has highlighted the importance of effective surveillance and containment strategies in public health. In this study, we examined the impact of county-level mandates on COVID-19 cases pre-post to the availability of vaccinations. We also emphasize the need for a dynamic model of policy, as changes in population behavior, conditions, and vaccination levels can alter policy effectiveness. Dr. Ertem will be talking about several models on different machine learning techniques to address several real-life problems in public health management. Mainly, she will describe an operations research-based approach can help improve efficiency in public health decisions. She will describe a new forecasting algorithm that uses multiple data sources to timely and accurately predict epidemic diseases. She will talk about her hierarchical framework uses multi-linear regression to combine forecasts from multiple data sources and greedy optimization with forward-selection to sequentially choose the most predictive combinations of data sources.

5 - Vaccine Allocation in Human Contact Networks: A Reinforcement Learning Approach

Ehsan Ardjmand, Ohio University, Athens, OH, United States

This research presents an innovative method for enhancing vaccine distribution within human contact networks to combat infectious diseases. The proposed approach integrates reinforcement learning and graph neural networks using a novel Guided Twin Delayed Deep Deterministic (GTD3) policy gradient technique. Unique to the methodology is the prioritization of individuals for vaccination based on their network position and role, incorporating a regularization term in the actor's loss function. Through extensive numerical experiments across diverse scenarios, the superiority of GTD3 over random and centrality-based methods in networks with varying degree distributions is demonstrated. Furthermore, GTD3 exhibits robust performance across networks of different sizes and configurations, highlighting its adaptability and real-world applicability. These findings offer significant insights for public health policy and resource allocation, presenting a promising framework for managing infectious disease outbreaks in complex and dynamic environments.

Data-Driven Crisis and Disaster Management

Contributed Session

Chair: FANG LIU, Durham University

1 - Privacy-Preserving Federated Learning for Human Activity Recognition

Setareh Kazemi Kheiri, State University of New York at Buffalo, Buffalo, NY, United States

Electrical line workers face significant occupational hazards, ranking among the top 10 most dangerous jobs in the United States. Ensuring their safety necessitates monitoring their activities without disrupting workflow. Wearable sensors offer a promising solution but raise privacy concerns. Addressing this gap, we propose a privacy-preserving framework using federated learning. A simulated lab experiment was conducted where participants performed various tasks of electrical line workers while wearing sensors on their dominant wrists. Acceleration data was collected, processed and used as an input to the federated weighted averaging method with adaptive learning rates. This method, compared to traditional machine learning approaches like k-nearest neighbors and support vector machines, yielded comparable accuracy (91%) while safeguarding participants' privacy. The federated learning framework allows for continuous optimization without compromising data privacy. Our findings demonstrate the feasibility of real-time activity recognition in hazardous environments. The implications extend beyond electrical line work. Our model can be applied in similar high-risk industries to monitor worker fatigue and prevent injuries. Moreover, it enables the development of ergonomic interventions tailored to real-time data, enhancing workplace safety and efficiency.

2 - Optimal Routing and Resource Allocation in Post-Disaster Scenarios through Multi-Objective Optimization and Multi-source Data Analytics

Zahra Hossein Pour, University of Arkansas, Fayetteville, AR, United States, Haitao Liao

The aftermath of hurricane events poses significant challenges for emergency management, particularly in maintaining effective transportation and resource allocation. This research proposes a novel framework that integrates multi-objective optimization with multimedia data analytics to enhance decision-making processes in real-time during disaster recovery. Our approach aims to simultaneously optimize multiple critical objectives: minimizing the time of response, maximizing the coverage of affected areas, and maximizing the utilization of available resources. Leveraging data from diverse sources, including social media, satellite imagery, and real-time traffic information, the framework provides a dynamic model to assess transportation disruptions and optimize routing strategies for emergency services effectively. The model incorporates machine learning algorithms to predict and adapt to changing conditions, ensuring optimal deployment of resources. This study will expand on previous efforts by incorporating a broader set of objectives and data sources, providing a more comprehensive and agile response mechanism. As a case study, the effectiveness of the proposed research framework can be validated using a recent hurricane event in which the objective is to significantly enhance the capabilities of emergency responders in areas impacted by the disaster.

3 - Fighting Fire with Data: Using SAS to Automate Identification of Fires in the Amazon.

Lavada Sharma, SAS Institute Inc., Raleigh, NC, United States

A fire burning in the Amazon to clear existing farmland is not nearly as devastating as a fire to clear newly deforested land, so the latter is what the Amazon Conservation Association concentrates its resources on identifying. But the ACA monitoring in search of these especially troubling blazes is currently through a manual and time-consuming review of fire alerts and satellite imagery. The SAS team was able to transform these two data sets into one and automate the generation of lists of new major fires, complete with precise coordinates of the locations that can be output into the ACA’s existing map application. In the end, the ACA said this automation took their science “to a whole other level.” SAS plans to continue assisting the ACA in this monitoring project throughout the upcoming fire season, which is expected to be even worse than usual. And this approach isn’t limited to the Amazon – it’s theoretically repeatable anywhere in the world.

4 - Optimizing JETP Implementation for Indonesia's Energy Transition

Kaarthigeswaran A Gnapathy, University of California, San Diego, La Jolla, CA, United States, Michael Davidson

The Indonesian Just Energy Transition Partnership (JETP) agreement has a stringent funding structure and does not include captive generation, which forms a significant share of greenhouse gas emissions in the country. A careful analysis is necessary to ascertain if the existing JETP agreements are helping or hindering Indonesia's energy transition. And what amendments are required between the funding partners and the government of Indonesia to ensure that JETP's energy transition goals are met.

To that end, we formulate a generation and transmission capacity expansion model that simulates JETP investments and provides insights into how the Indonesian power system would look post-JETP. This model will be a least-cost optimization model where we find the optimal generation investments to meet the projected demand in the major islands of Indonesia. The capacity built and retired for generation, transmission, and storage, along with the generation produced by the generators, will be the key decision variables for this model. We utilize publicly available data from the Indonesian government documents and the JETP secretariat and the model would introduce multiple scenarios

This study aims to explore a funding structure different from the original JETP and identify any future funding partners or collaborators that may help Indonesia achieve its JETP goals. This study also hopes to inform the International Partners Group (IPG) and Glasgow Financial Alliance for Net Zero (GFANZ) that funds JETP, the government of Indonesia, and electricity market participants in Indonesia about possible amendments to the JETP agreement and policy recommendations.

5 - Integrated Virtual Stockpile Pooling and on-Event Retrieval for Efficient Emergency Response

FANG LIU, Durham University, Durham, United Kingdom, Minxuan He, Jing-Sheng Song

To mitigate warehousing and spoilage costs in emergency supply stockpiling, governments often partner with private companies to distribute emergency supplies across various locations in the commercial supply chain for regular demand rotation. Commonly, a ``red line'' is assigned to each location, with inventory below this line reserved solely for emergencies. Previous literature has proposed a Virtual Stockpile Pooling (VSP) strategy that dynamically adjusts red lines among the locations based on real-time demand information, omitting the emergency retrieval process. This study introduces an Integrated Virtual Stockpile Pooling and On-Event Retrieval (VSPR) strategy that refines VSP by incorporating emergency retrieval costs into its design. We present a novel ranking method to solve VSPR's three-stage optimization process, leading to a collaborative base-stock system, a priority-based red-line reassignment, and a greedy algorithm for efficient supply retrieval. We show that VSPR strategically reserves supplies at ``key locations'', optimizing cost and response efficiency. A case study demonstrates that, compared with VSP, VSPR has the potential to reduce operational costs by up to 13.8% while enhancing service levels by up to 4.9%. VSPR's applicability extends to many other contexts, including resilient supply chain management, healthcare operations, energy and natural resource management, and military logistics.

Summit - 332

Optimization for Freight Transportation

Contributed Session

Chair: Amir-Behzad Samii, Vlerick Business School, Brussels, Belgium

1 - Untangling the global supply chain with artificial intelligence

Hiroki Oshima, Hitachi America, Ltd. , Santa Clara, CA, United States, Misaki Mito, Chi Heem Wong, Chakrabarti Arnab

The global supply chain faces challenges from multiple dimensions, including geopolitical tensions, environmental changes, and financial threats. Dealing with these risks requires a thorough understanding of both the logistical network and the interaction between the participants. Unfortunately, it is difficult to get visibility into the shipping process or the producer-supply network. In this presentation, we demonstrate three of our efforts to shed light on the problems faced by industry and develop solutions to address them. First, we build a temporal graph network to predict the production functions of international firms and the transactions between them. By doing so, we can better simulate impacts on the supply chain network. Second, we introduce “sensor-less” monitoring technology that can estimate internal conditions of shipping containers using meteorological data which obviates the need for cargo sensors. A visual demonstration of a working sensor-less prototype will be shown in the presentation. Third, we develop an event analysis framework to detect transportation disruptions in real-time, utilizing AIS data to estimate the location, date, and impact of the transportation disruption based on the vessel's behavior. Our technology is targeted towards tracking and prevention of cargo accumulation due to transport delays, which can lead to massive losses in accidents or disasters. These systems, working in concert, can assist companies to lower their cost of shipping, improve the quality of their services, and mitigate disruptions in the supply chain.

2 - Risk-Informed Stochastic Programming with Applications to Inland Flash Flooding of Roadway Freight Networks

Beau Groom, University of Tennessee, Knoxville, TN, United States, Mingzhou Jin

Annual freight volume is projected to grow by 50% over the next 15 years in the US, which will increase the importance of the supply chain to the economy and national security. This will exacerbate the impacts of climate change on the supply chain, a relationship that has not been well-defined for inland regions. More frequent high-intensity storms will lead to an increase in flash flooding, causing both short-term and long-term disruptions to the road network. Traditional decision-making frameworks are unable to deal with these high-impact, low-probability events, typically choosing to ignore them instead. Our proposed research relaxes the assumption of known probability distributions and uncertainty sets while incorporating the risk postures of decision makers by developing a novel risk-informed stochastic programming (RISP) model for decision making in the face of extreme events. The RISP model will be applied to the threat posed to road freight transportation by climate-change-induced flash flooding to identify strategic investment decisions to ensure supply chain performance in the midst of disruptions.

3 - A Multimodal Multicommodity Network Equilibrium Model with Service Capacity and Bottleneck Congestion for China-Europe Containerized Freight Flows

Xinyan Li, Shanghai Jiaotong University, Shanghai, China, People's Republic of

As a traditional way for transporting containerized cargoes, international liner shipping has long played a dominant role in the China-Europe freight transportation market. In recent years, China Railway Express has offered a new and competitive freight transportation option. To

provide a holistic computational tool that can predict and analyze the spatial distribution of containerized freight flows and suggest strategic transportation infrastructure and service expansion options, this paper develops and implements a multimodal multicommodity freight transportation network equilibrium model, based on a newly constructed supernetwork integrating international liner shipping lines, international freight rail services, and international and domestic highway networks in relevant countries. The combined transportation mode-route choice behavior of individual shippers is characterized by the multinomial logit model, where the values of time of different commodity categories are included in its utility functions. The congestion effects arising from bottleneck facilities along liner shipping and freight rail lines are first captured by queueing models and then approximated by polynomial delay functions, while the accommodation capacity of individual service lines is explicitly embedded into the model as hard constraints. This supernetwork equilibrium model is tackled by a subgradient algorithm in the Lagrangian relaxation framework embedding a disaggregate simplicial decomposition algorithm. Computational experiments are conducted with a multi-layer, hetero-structure set of supply and demand data. The preliminary results exhibit the computational performance of the solution procedure and reveal the variation of congestion levels of bottleneck facilities, capacity usage profiles of service lines, and competitiveness conditions between liner shipping and freight rail services.

4 - Physical Asset Criticality Index in Energy Supply Chains

Amir-Behzad Samii, Vlerick Business School, Brussels, Belgium, Raf Bellers

Disruptions can interfere with the pace of the energy transition, delaying decarbonization and other urgent actions against climate change. As a critical player in the energy supply chain, the Distribution System Operator (DSO) must fortify its operations against endogenous and exogenous supply risks, look for ways to compile knowledge and build relevant indicators to prompt an adequate response strategy. Thus, the talk focuses on deriving an asset criticality index tailored for DSO operations from a forecasting and inventory management perspective. By providing a quantitative measure of the criticality of each asset, the index allows the DSO to fine-tune internal processes and prioritize resources based on their strategic importance, ensuring that high-priority assets receive the necessary attention. Regarding inventory management, critical assets may require higher safety stock levels or closer monitoring to prevent disruptions.
The proposed asset criticality index includes several risk dimensions. We started by identifying key parameters: availability of alternative suppliers for each stock-keeping unit, the lead time, and on-time in full delivery performance that contribute to the supply risk dimension of the index. Following discussions with key experts for the DSO, we decided to what extent these parameters, and possibly others, represent risk drivers for the DSO operations and how they contribute to the index. The criticality index can also be expanded to include other vulnerabilities or risk dimensions specific to the energy supply chain, such as raw material risks, ensuring that the critical index safeguards against disruptions and actively contributes to the low-carbon transition.

1 - Balancing Prepositioning and Relocation for Efficient Compound Flood Relief

Muhammad Naiman Jalil, College of Business and Economics, United Arab Emirates University, Al Ain, United Arab Emirates, Syed Tariq, Muhammad Adeel Zaffar

Floods affect more people every year than any other natural disaster. Compound flooding is when multiple flooding events exacerbate the impact and duration of a flood. This paper studies relief logistics for compound flooding through the case of floods in Sindh province of Pakistan in 2010. The problem is treated as time-varying flows of relief goods from relief warehouses through periodic relief caravans to relief camps or storage close to them; and flows of affected people from shelter sites closest to them to more accessible shelter sites. Results highlight factors that reduce logistics cost and improve demand fulfillment including prepositioning relief goods near shelters, affected people relocation, frequent relief deliveries, and smaller storage modules that reflect relief demand between consecutive relief deliveries more closely. Comparative results indicate that relocation of affected people can be as cost effective as prepositioning of relief goods depending on optimal placement of relief warehouses. In case of no prepositioning, affected people relocation becomes an instrument of choice compared to relief goods transportation on longer routes during compound flooding. Temporal analysis show that affected people relocation is most effective in early stages of compound flooding, whereas goods transportation is preferred in later stages. Overall results suggest positioning of relief goods is most effective in the preparedness phase of disaster relief, relocation is most effective in the early response stage and goods transportation takes up most of the logistics activities towards late response.

2 - Boeing 787 Dreamliner Program Supply Chain Assessment

Zhiyuan Li, Southeast University, Nanjing, China, People's Republic of

This paper examines the supply chain dynamics of the Boeing 787 Dreamliner program, focusing on its global outsourcing and multi-level integration. It evaluates the effectiveness, efficiency, and feasibility of this supply chain model, highlighting the need for enhancements in product development and information transfer efficiency. Recommendations include the establishment of a lean supply chain management model, implementing supplier performance evaluation and incentive mechanisms, creating a global collaborative information platform, fostering collaboration with competitors, involving experts in supplier design and production, and prioritizing independent research and development alongside intellectual property protection.

3 - A Framework to Organize Public Transport-based Crowdshipping

Meijing Zhang, Singapore University of Technology and Design, Singapore, Singapore, Lynette Cheah

Enabled by the steady growth of e-commerce, there is a surge in demand for parcel shipments in many cities. With increasing calls for sustainable freight transport, logistics service providers are facing the need to address these challenges. Crowdshipping presents an innovative solution by involving members of the public to fulfill parcel deliveries, ideally along their pre-committed journeys. This paper aims to propose a comprehensive framework to organize public transport-based crowdshipping by integrating the use of parcel lockers. This approach allows public transport passengers to serve as crowdshippers, ensuring that parcel delivery demand aligns with crowdshipper availability and willingness to participate, while considering locker capacity constraints. The framework involves formulating and solving assignment and vehicle routing problems, incorporating matching for parcels and lockers, as well as using an iterative heuristic algorithm for optimal locker selection. The feasibility of the framework is demonstrated using real-world data, revealing significant benefits. By comparing a carrier's performance with and without engaging crowdshippers, the results indicate that delivery vehicle kilometers traveled and associated air emissions can be reduced by up to 30%. This reduction only requires redirecting less than 9% of parcels to crowdshipping. Overall, crowdshipping utilizing public transport has strong potential to be a sustainable method for fulfilling urban logistics in densely populated cities.

4 - Brand Authenticity as a Driver of Brand Loyalty in Frozen Foods sector: An Investigation of Brand Involvement and Customer Satisfaction as Mediators

SAQIB SHAHZAD, Sichuan University, Chengdu, China, People's Republic of, Adnan Sarwar, Li Shan

Purpose: The purpose of this study is to investigate the effect of brand authenticity on consumer brand loyalty in the Pakistani frozen food industry sector in the light of Stimulus Organism Response (SOR) Theory.

Design/Methodology/Approach: The quantitative approach utilized a survey questionnaire to acquire the perceptions of customers. A simple random technique was used to collect data. A total of 255 questionnaires were analyzed, and the response rate was 46.36%.

Findings: A structural and measurement model was constructed through Smart PLS-4. The findings indicated that brand authenticity has a positive effect on brand loyalty in the Pakistani frozen food industry. Results further proved that brand involvement has a full mediation effect, and customer satisfaction has a partial mediation effect.

Originality/value: This study investigates the impact of brand authenticity on brand loyalty in the frozen food industry in Pakistan. It specifically examines the mediating effects of brand involvement and customer satisfaction, which have not been extensively studied in previous research.

Keywords: brand authenticity, brand loyalty, SOR theory, brand involvement, customer satisfaction

5 - Empowering SMEs: Harnessing Collaborative Capability Marketplaces and AI for Supply Chain Transformation

Fatima Gillani, Nottingham Business School, Nottingham Trent University, Nottingham, United Kingdom, Zeng Fan, Xiao Ma, Jay Bal

Small and Medium Enterprises (SMEs) are pivotal to the global economy, yet they frequently face challenges in the rapidly changing business landscape and ongoing global crisis to scale their operations and penetrate new markets due to rigid B2B supply chain dynamics. In this realm, SMEs and their supply chains need new ways of operating that can ensure their survival and competitiveness. This study introduces a competence matching platform named the Collaborative Capability Marketplaces (CCM), which integrates advanced digital AI platforms, representing a significant paradigm shift, facilitating SMEs' connections with potential partners and engagement in larger projects. Employing a structured analytical approach, the impact of this AI-driven e-marketplace is evaluated through data from seven case studies. The findings identify two key mechanisms—competence malleability and combination—through which firms can improve their adaptability and gain a competitive edge in the marketplace. These mechanisms empower SMEs to navigate the complexities of modern markets with greater agility and foresight, allowing them to continually evolve their business models and operational tactics. The CCM acts as a transformative platform and enables SMEs to effectively showcase their competencies and access a broader range of project opportunities. The integration of Natural Language Processing aids in more accurate competency profiling and enhances the identification of suitable public and private projects; AI-based competence matching in the platform supports the development of new supply networks capable of managing high-value projects. These advancements strengthen SMEs' market positions by aligning their resources more closely with their strategic goals and market demands.

Optimization and Pricing Models for Digital and Retail Markets

Contributed Session

Chair: Jisoo Park, Georgia Institute of Technology, Atlanta, GA, United States

1 - AI-Enabled Smart Retail Solutions for Improving Customer Experience Management

Jongsawas Chongwatpol, NIDA Business School, National Institute of Development Administration, Bangkok, Thailand

The challenge for physical retail stores is to offer unique value that sets them apart from the convenience of online shopping. How can AI solutions be designed and implemented effectively to manage and support the in-store customer journey and to understand the role of the customer experience at each stage of the journey? This study presents a design journey for AI implementation to understand and improve the in-store customer shopping experience by proposing a computer vision AI-based track and traceability framework with motion and emotion analysis. This study adopts the design thinking process to ensure that any challenges and failure factors in AI solutions are tackled in the proof-of-concept stage, which focuses on generating and testing the ideas. The case, presented in this study, leverages, and integrates the wealth of information made available by face recognition technologies into marketing strategies for personalizing advertisements and video content, tracking marketing and sales leads, tracking customers' motions and emotions, automating face recognition payment, and personalizing follow-up campaigns based on customers' preferences and in-store shopping habits. The contribution of this study is the proposed computer vision-AI based track and traceability system with motion and emotion analysis, which allows store managers or marketing analysts to understand customer preferences and purchasing behaviors by improving information visibility by tracking customers' movements and activities in the store.

2 - Assortment Planning Optimization under Uncertainty with Customer-driven Product Substitution

Jisoo Park, Georgia Institute of Technology, Atlanta, GA, United States, Walid Klibi, Benoit Montreuil

The evolving retail landscape, marked by increasing production costs and resource constraints, highlights the need for assortment planning decisions made with supply chain considerations. Traditionally, retail product manufacturers have assortment decisions driven by marketing, yet these decisions are intricately linked to operational aspects such as procurement, production, and inventory planning. Given the challenges posed by the unpredictable dynamics of today's retail market, we propose an integrative optimization model to address the assortment planning problem in a make-to-stock environment. We estimate customer substitution behavior with a closed-form expression based on the multinomial logit model and leverage these behaviors from the procurement and manufacturing stages to mitigate supply and demand uncertainties. Our framework addresses the challenge of aligning product offerings with supply chain capabilities and customer preferences to maximize expected profit while considering procurement and production capacity constraints. We formulate the problem as a multi-stage stochastic program with uncertain and time-varying demand, represented by multi-period look-ahead forecasts, as commonly observed in practice. Results are presented using data from an e-commerce furniture manufacturer and retailer.

3 - Co-creation and Pricing Issues in 3D Printing-as-a-Service

Jishnu Hazra, Indian Institute of Management Bangalore, Bangalore, India, Tarun Jain, Ram Gopal

The advent of 3D printing technology has facilitated new avenues for collaborative product design endeavors between manufacturers and customers. The manufacturers now leverage the 3D Printing-as-a-Service (3DaaS) model by renting out 3D printers. In this paper, we attempt to address the following research questions: What pricing model is suitable for offering 3DaaS? How do factors such as the degree of design customization and complexity impact the pricing strategy employed by the 3DaaS firm?

4 - Gig Outsourcing by Freelancers in Online Labor Markets

Sambit Tripathi, Portland State University, Portland, OR, United States, Prasanna Karhade, Amit Deokar

We explore the outsourcing strategies of freelancers in online labor markets. Literature on online labor markets considered buyers and freelancers as separate entities with specific characteristics. Studies primarily focus on how buyer attributes, freelancer attributes, and gig attributes can efficiently match freelancers and buyers. Yet, online labor markets enable buyers and freelancers to access the platform as users. Users can switch roles between buyer and freelancer in the platform. In this study, we analyze the buying and freelancing activities of the same user in an online labor market to establish the motivations of freelancers for switching to buyers. This phenomenon provides opportunities for freelancers to act as buyers and outsource specific tasks to other freelancers on the platform.

We capture users' buying and freelancing activity from a global freelancer marketplace. Next, we perform a natural language processing method to determine the similarity in the tasks completed and tasks outsourced by the same user. Our results show that freelancers conduct outsourcing strategies by hiring other freelancers to do their core and peripheral activities. This study contributes to the literature on online labor markets by introducing freelancers as buyers and explaining their outsourcing strategies. Practical implications of our research include addressing how hiring decisions are made by freelancers while outsourcing tasks to other freelancers.

Co-Chair: Zijin Zhang, Ross School of Business, University of Michigan, Ann Arbor, MI, 48104, United States

2 - Can Price Discrimination be Progressive?

Enfeng Xing, Tianjin University, Tianjin, China, People's Republic of, Michael Hamilton, Max Biggs, Titing Cui

Third-degree price discrimination, the practice of selling similar goods and services at different prices across various market segments, is a well-studied strategy aimed at maximizing firm revenue. The common view of price discrimination holds that it is detrimental to consumers. Price discrimination, however, can in some instances enhance consumer welfare. In this work we re-examine the impact of price discrimination on consumer welfare, paying special attention not just to aggregate gains in surplus but looking specifically at which customers in the market benefit. We highlight this by studying revenue-maximizing segmentation and price effects through the lens of proportional customer surplus which is the percentage gain in utility for a customer relative to their willingness-to-pay. Under proportional surplus, gains made by the least well-off in the market are given additional weight making it a more progressive measure of redistribution. For the case of linear demand, we show that under the revenue-maximizing segmentation and pricing, the proportional surplus increases for modest levels of price discrimination. We then generalize these results beyond linear demand, suggesting that modest levels of price discrimination can often improve relative welfare in the market even if in aggregate the total surplus decreases.

3 - Designing Pandora's Box: Personalized Rankings in Two-sided Marketplaces

Shreyas Sekar, University of Toronto - Rotman School of Management, Toronto, ON, Canada, Yiangos Papanastasiou

With the growth of e-commerce, rankings and recommendations have emerged as one of the primary levers used by two-sided marketplaces to match demand and supply. Much of the work on this topic has centered around constructing personalized rankings aimed at maximizing specific objectives (e.g., revenue, purchase probability), often assuming that the supply of sellers is fixed. However, these approaches do not account for: a) consumers' incentives to inspect products in the same order as the ranking; b) the impact rankings have on sellers' revenue and their decision to enter the platform.

In this work, we present a comprehensive model of product rankings that account for the incentives on both sides of the market. We show that traditional greedy or personalized ranking policies that myopically optimize revenue end up being sub-optimal as niche sellers are better off not joining the platform. Instead, we present randomized, incentive-compatible product ranking policies that achieve the first-best outcome by balancing the mix of mainstream and niche sellers in the top positions. Overall, our work presents a new lens to examine product ranking policies in two-sided marketplaces, and emphasizes the market-building nature of product rankings.

4 - Leveraging Offline Data for Online Decision-Making in Bayesian Multi-Armed Bandits

Wenxin Zhang, Columbia University, NEW YORK, NY, United States, Will Ma, Santiago Balseiro

This paper investigates using offline data for online sequential decision-making in Bayesian multi-armed bandit problems. We study a finite-horizon model with Bernoulli rewards, where the reward probabilities of each arm are independently drawn from unknown prior distributions. The offline dataset contains n MAB instances, each of which is a sequence of T arms pulled by some historical policies and their associated reward observations. We assume the prior is shared across the historical instances and the online instance. Empirical risk minimization is infeasible because of the lack of counterfactuals and the large size of the policy class. We introduce a dynamic programming formulation designed to derive the optimal Bayesian policy, where the expected reward of any policy is expressed as a linear combination of expectations of functions of arm reward probabilities. We then replace these theoretical expectations with unbiased estimators constructed from the data. We show the DP is solvable in polynomial time w.r.t. T, and the cumulative reward of the resulting policy converges to the optimal Bayesian policy at rate $\tilde{O}(n^{-1/2})$. Our algorithm allows a broad class of historical policies, so long as they “stay on the winner” and initially play all arms with positive probability.

1 - Consistent Assortment Optimization Under the Mnl with Exogenous Data

Carlos Cardonha, University of Connecticut, Storrs, CT, United States, Aritanan Gruber

This work investigates the Assortment Optimization Problem under the Multinomial Logit choice model in scenarios where the firm does not know the attractiveness factors associated with each product. In our model, the firm relies on exogenous data consisting of the assortments offered by other firms and random variables defining a set of conversion rates, which are multiplicative factors indicating how the products' attractiveness adopted in the external assortments differ from the respective values for the firm. The notion of optimality is nuanced in this model, so we focus on consistent assortments instead, i.e., we wish to make assortment decisions that do not conflict with exogenous data. We investigate different solution techniques for the problem based on assumptions about the conversion rates. We show that the expectation-based deterministic formulation of the problem can be solved efficiently. We also study a fully-separable probabilistic-constrained formulation, showing that such problems can be cast as second-order cone programs when the conversion rates are normally distributed. Our results show that the model does not require unrealistically large amounts of exogenous data to deliver accurate results, thus providing evidence that our framework can be adopted in practice.

2 - Multi-Product Dynamic Upgrades

Xiao Zhang, Saint Louis University, Saint Louis, MO, United States, Justin Goodson, Tiancheng Zhao

Upgrades in travel industry are often static and offered either at the booking time or at the check-in time. In this paper, we study dynamically-offered upgrades by a multi-product firm via notifications (e.g., emails and push notifications) between the booking and the check-in times. We investigate a general multi-level upgrade policy in which a customer may be upgraded to any better products and two single-level upgrade heuristics which are less computationally intensive. Both heuristics have clean structures respectively and are easy to implement. We adopt discrete convex analysis concepts into our analysis and identify monotonicity properties for the optimal single-level upgrade policies.

3 - Pricing Analytics with Shape-Restricted Demands

Jingren Liu, National University of Singapore, Singapore, Singapore, Hanzhang Qin, Mabel C. Chou

We consider a fundamental problem in revenue management: feature-based pricing, where a firm needs to make a pricing decision to maximize the expected revenue for a single product based on feature information. Historical prices, covariates, and sales are available for demand estimation. Our model assumes a linear relationship between price and demand while simultaneously capturing the impact of covariates through a nonparametric shape-restricted function. We develop a Three-Step Semi-Parametric Estimation algorithm to estimate the demand and foster provably near-optimal data-driven pricing decisions. From a non-asymptotic perspective, we derive finite sample regret bounds, showcasing the efficacy of our algorithm in achieving near-optimal revenue, even under potential misspecification of the demand model. The numerical results demonstrate that the decision performance of our algorithm is comparable to the Double Machine Learning method, while significantly outperforming a naive two-step iterative learning method as well.

4 - Assortment Planning in the Presence of Buy Online, Pick-up in-Store

Venus Lo, City University of Hong Kong, Kowloon Tong, Hong Kong

We consider an assortment planning problem in an on omnichannel operations where customers can purchase online and pick-up in-store (BOPS) shortly after placing an order. Retailers like to offer BOPS because customers may purchase add-on products upon when they arrive to pick up their orders and they do not need to ship products directly to customers. However, the retailer also incurs a cost for offering products under BOPS because employee manpower is needed to pick out these orders from the shelves. Hence, BOPS could be unprofitable if customers do not purchase add-on products or if the cost to prepare these orders are high. We present an approximation algorithm to show how a retailer can choose a good assortment to designate as BOPS in an online store so that he can attract customers to the physical store and maximize profitability.

Online Learning in Games and Auctions

Invited Session

Revenue Management and Pricing

Chair: Christian Kroer, Columbia University, New York, NY, United States

Co-Chair: Rachitesh Kumar, Amazon, Seattle, WA

1 - Improved Rates for No-Regret Learning in General Games

Gabriele Farina, MIT, Cambridge, MA, United States

A recent line of work has established uncoupled learning dynamics such that, when employed by all players in a game, each player's regret after T repetitions grows polylogarithmically in T, an exponential improvement over the traditional guarantees within the no-regret framework. However, so far these results have only been limited to certain classes of games with structured strategy spaces---such as normal-form and extensive-form games. The question as to whether O(polylog T) regret bounds can be obtained for general convex and compact strategy sets---which occur in many fundamental models in economics and multiagent systems---while retaining efficient strategy updates is an important one. After recalling recent advances, in this talk we answer the question in the positive by establishing uncoupled learning algorithm with O(log T) per-player regret in general convex games, that is, games with concave utility functions supported on arbitrary convex and compact strategy sets. Our learning dynamics are based on an instantiation of optimistic follow-the-regularized-leader over an appropriately lifted space using a self-concordant regularizer that is, peculiarly, not a barrier for the feasible region. Further, our learning dynamics are efficiently implementable given access to a proximal oracle for the convex strategy set, leading to O(loglog T) per-iteration complexity. Even in those cases where prior results apply, our algorithm improves over the state-of-the-art regret bounds either in terms of the dependence on the number of iterations or the dimension of the strategy sets.

Based on joint work with Ioannis Anagnostides, Haipeng Luo, Chung-Wei Lee, Christian Kroer, and Tuomas Sandholm. Paper: https://openreview.net/pdf?id=SiSv_XDMksL

2 - Smoothed Nash Equilibria: Algorithms and Complexity

Abhishek Shetty, University of California, Berkeley, Berkeley, CA, United States, Konstantinos Daskalakis, Noah Golowich, Nika Haghtalab

A fundamental shortcoming of the concept of Nash equilibrium is its computational intractability: approximating Nash equilibria in normal-form games is PPAD-hard. In this talk, inspired by the ideas of smoothed analysis, we present a relaxed variant of Nash equilibrium called σ-smooth Nash equilibrium, for a smoothness parameter σ. In a σ-smooth Nash equilibrium, players only need to achieve utility at least as high as their best deviation to a σ-smooth strategy, which is a distribution that does not put too much mass (as parametrized by σ) on any fixed action. We show that σ-smooth Nash equilibria have superior computational properties to Nash equilibria. We will present various algorithmic results that establish that σ-smooth Nash equilibrium can be computed in polynomial time, both in terms of query and computational complexity. These results stand in contrast to the optimal algorithm for computing ϵ-approximate Nash equilibria, which cannot run in faster than quasipolynomial-time. We will also complement our upper bounds by showing that when either σ or ϵ is an inverse polynomial, finding a weak ϵ-approximate σ-smooth Nash equilibria becomes computationally intractable.

3 - Learning Dynamics in Auction Games

Martin Bichler, Technical University of Munich, Garching B. München, Germany

Equilibrium problems in Bayesian auction games can be described as systems of differential equations. Depending on the model assumptions, these equations might be such that we do not have a rigorous mathematical solution theory. The lack of analytical or numerical techniques with guaranteed convergence for the equilibrium problem has plagued the field and limited equilibrium analysis to rather simple auction models such as single-object auctions. Recent advances in equilibrium learning led to algorithms that find equilibrium under a wide variety of model assumptions. We analyze first- and second-price auctions where simple learning algorithms converge to an equilibrium. The equilibrium problem in auctions is equivalent to solving an infinite-dimensional variational inequality (VI). Monotonicity and the Minty condition are the central sufficient conditions for learning algorithms to converge to an equilibrium in such VIs. We show that neither monotonicity nor pseudo- or quasi-monotonicity holds for the respective VIs. The second-price auction's equilibrium is a Minty-type solution, but the first-price auction is not. However, the approach allows us to get ex-post guarantees for gradient-based algorithms. We show that the Bayes--Nash equilibrium is the unique solution to the VI within the class of uniformly increasing bid functions, which ensures that gradient-based algorithms attain the equilibrium in case of convergence, as also observed in numerical experiments.

4 - Robust Budget Pacing with a Single Sample

Rachitesh Kumar, Columbia University, New York, NY, United States, Santiago Balseiro, Vahab Mirrokni, Balasubramanian Sivan, Di Wang

Advertising is the economic engine of the internet. Online advertising opportunities are predominantly sold through real-time auctions: whenever a user visits the platform, an auction is run among interested advertisers, and the winner gets to display their ad to the user. Motivated by online advertising, we develop data-driven algorithms for bidding in repeated auctions under a global budget constraint. We study a non-stationary stochastic model of sequential auctions, which despite immense practical importance has received little attention, and propose a natural algorithm for it. With access to just one historical sample per auction/distribution, we show that our Dual FTRL algorithm attains (nearly) the same performance as that possible under full knowledge of the distributions, while also being robust to distribution shifts between the sampling and true distributions.

1 - Oligopolistic Competition in Online Marketplaces: Equilibrium Analysis and System Coordination

Xinyi Zhou, The Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Ruxian Wang, Guillermo Gallego, Lijian Lu

Two-sided marketplaces have grown rapidly over recent years and are ubiquitous in daily life. One important challenge is to design the marketplace to support the sustainability and efficiency of the ecosystem. This paper investigates the roles of selling formats in a two-sided marketplace with many sellers selling substitutable products on a common retailing platform. We formulate the strategic interactions between sellers and the platform in a supply function competition framework, in which each seller offers a schedule of quantity and payment that is a general function of quantities. We show that a contribution-based model (CBM), whereby the payment for each seller is based on the seller's contribution, is the only equilibrium for the supply function. We also show that the CBM results in a coordinated system achieving the first-best outcome, which is not attained under the other two widely observed schemes, reselling and agency selling. We propose a variant of CBM that yields a stable, economical, coordinated, and individually aligned outcome for all firms in the marketplace. Our findings could provide useful guidance for the design of strategic partnerships between firms in a two-sided marketplace.

2 - Room Pricing with Interdependent and Heterogeneous Price Sensitivities

Svetlana Riabova, University at Buffalo, Buffalo, NY, United States, Andrew Vakhutinsky, Natalia Kosilova, Jose Walteros

We present a data-driven approach to revenue management in the hospitality
sector. Our developments are focused on designing optimal hotel pricing policies in the presence of confounders, heterogeneity in price sensitivities, and interdependencies between the prices of different room types. The proposed approach leverages recent developments in Double/Debiased Machine Learning to develop a predictive model aimed at obtaining unbiased treatment effect estimates in the presence of confounders. We integrate the resulting predictive model into an optimization framework to determine optimal pricing policies. We tested our approach using a case study designed to emulate real scenarios that consider critical factors such as seasonality and heterogeneous customer preferences and show that the proposed model can efficiently identify the effects of the pricing policies on customer booking decisions.

3 - Contextual Dynamic Pricing: Algorithms, Optimality, and Local Differential Privacy Constraints

Zifeng Zhao, Mendoza College of Business, University of Notre Dame, Notre Dame, IN, United States

We study the contextual dynamic pricing problem where a firm sells products to T sequentially arriving consumers that behave according to an unknown demand model. The firm aims to maximize its revenue, i.e. minimize its regret over a clairvoyant that knows the model in advance. The demand model is a generalized linear model (GLM), allowing for a stochastic feature vector in $\mathbb R^d$ that encodes product and consumer information. We first show that the optimal regret is of order $\sqrt{dT}$, up to a logarithmic factor, improving upon existing upper bounds in the literature by a $\sqrt{d}$ factor. This optimal rate is materialized by two algorithms: a confidence bound-type (supCB) algorithm and an explore-then-commit (ETC) algorithm. A key insight of our theoretical result is an intrinsic connection between dynamic pricing and the contextual multi-armed bandit problem with many arms based on a careful discretization. We further study contextual dynamic pricing under the local differential privacy (LDP) constraints. In particular, we propose a stochastic gradient descent based ETC algorithm that achieves an optimal regret upper bound of order $d\sqrt{T}/\epsilon$, up to a logarithmic factor, where $\epsilon>0$ is the privacy parameter. The regret upper bounds with and without LDP constraints are accompanied by newly constructed minimax lower bounds, which further characterize the cost of privacy. Extensive numerical experiments and a real data application on online lending are conducted to illustrate the efficiency and practical value of the proposed algorithms in dynamic pricing.

4 - Product Display Optimization with Quality Uncertainty and Return

Yang Lu, University of Science and Technology of China, Hefei, China, People's Republic of, Ruxian Wang, Xiaoming Yan, Yugang Yu

Display quality refers to product information such as the images and textual descriptions of product quality presented to consumers shopping online, and can directly influence market demand during the sales phase and product returns during the after-sales phase. In this paper, we investigate the product display optimization problems on display quality, pricing, and assortment planning, in consideration of product quality uncertainty and consumers' return behavior. We employ the widely used multinomial logit (MNL) model to characterize the impact of display quality on consumer choices. In particular, we incorporate display quality into the utility function under the MNL model and characterize online consumers' purchase and return behavior that is largely affected by display quality. We then conduct joint optimization analysis on assortment planning, display quality, and pricing. Comparative statics elucidates the relationship between pricing and display quality decisions. Surprisingly, we reveal that higher product price does not necessarily lead to higher display quality unlike the classical MNL model. Then we propose an efficient method to determine the optimal offer set that involves assessing whether the conservative retention rate of a product exceeds 0. Because of its high impact on both early market demand and later consumer return behavior, display quality alters the pricing and assortment planning structure of the retailer. Moreover, we find that optimizing display quality presents an opportunity to achieve a win-win outcome for both the retailer and consumers, which could serve as a reference for market regulation.

1 - Enhancing Refugee Resettlement: An Integrated Decision-Making Approach for Assignment

Jesica de Armas, Universitat Pompeu Fabra, Barcelona, Spain, Valérie Belanger, Marie-Ève Rancourt, Gilbert Laporte

Over the past few years, there has been a notable surge in asylum applications within the European Union (EU), underscoring the urgency for effective decision-making in the resettlement process. This study delves into the predominant outcome for asylum seekers—attaining refugee status—and the subsequent resettlement process that facilitates their transition from an asylum-providing nation to a host country. Successful integration stands as a pivotal factor in ensuring favorable outcomes for both refugees and host nations alike. Achieving this requires concerted efforts from all stakeholders, encompassing the adaptability of refugees and the preparedness of host communities. Through the National Integration Evaluation Mechanism project, integration outcomes for refugees across 15 EU member states are comprehensively assessed using a set of integration indicators. The resettlement process is further influenced by the priorities of host countries and the preferences of refugees. However, a comprehensive optimization framework that amalgamates these diverse dimensions for decision-making support is currently lacking. To address this gap, this research introduces a multiobjective decision-making system that incorporates factors such as integration potential, host countries' priorities, and refugees' preferences, while also considering quotas and analyzing various scenarios. By providing organizations with informed decision-making capabilities, this system has the potential to be seamlessly integrated into existing information systems. Ultimately, this research contributes towards tackling the intricate challenges associated with refugee resettlement, with promising societal implications.

2 - Shifts in Weather Patterns: A Comprehensive Study of Temperature, Precipitation, and Extreme Events

Alexandros Paparas, Eastern Washington University, Spokane, WA, United States, Stella Alevra, S.B. Fotopoulos

The study examines shifts in climatic variables—temperature, precipitation, and extreme events—across 120 stations in the contiguous United States. Our primary goal is to understand climatic changes and their impact on human life and ecosystems. Through multivariate change point analysis, we identify significant shifts in weather patterns. By adopting this multivariate approach, we gain nuanced insights into dependencies among cities, offering a better understanding of regional climatic variations across diverse geographical landscapes. Our primary method for estimating and inferring change points involves an iterative procedure that combines squared loss-based change point recovery with ℓ_1-regularized squared loss recovery of mean estimates. Although initially developed for single change points, we extend our method to handle multiple change points using the principle of binary segmentation. Our dataset spans from 1948 to 2023, providing comprehensive temporal and geographical coverage. It includes major metropolitan areas and rural surroundings, offering a holistic representation of climatic conditions. Understanding these patterns is crucial for adaptation, timely interventions, and mitigating extreme climatic events.

1 - The Effect of Urban Infrastructure Change on Movement: Investigating Impacts on Visitor Patterns, Business Activities, and Traffic in Seattle after the COVID-19 Pandemic

Grace Jia, University of Washington, Seattle, WA, United States, Ekin Ugurel, Steve Mooney, Jon Froehlich, Cynthia Chen

The COVID-19 pandemic and work-from-home policies disrupted retail businesses and led to deserted downtowns. However, this crisis also spurred municipalities and businesses to innovate their urban infrastructure, aiming to adapt to the new normal and encourage pedestrian activity in public spaces. This research aims to investigate the effects of these urban infrastructure innovations on visitor patterns, business activities, and traffic patterns in Seattle, a city that implemented various changes during the pandemic. Leveraging longitudinal data sources including app-based GPS data, Google Street View, and business data, our study quantifies changes at a block-level resolution. We develop novel algorithms to clean and explore these data, addressing issues such as biases and sparsity. Furthermore, we develop methods to quantify changes in urban infrastructure and assess their impact on the region's transportation system. Our study site, the City of Ballard, is a vibrant business district and has seen significant changes during the COVID period. Additionally, we will identify additional sites in the region to capture a diverse range of built environment characteristics. By answering critical questions about the effects of urban infrastructure innovations, our research will provide valuable policy guidance to local jurisdictions.

2 - Enhancing Urban Rail Transit Planning with a Vec-to-Seq Neural Network

Zhuo Han, University of Massachusetts Amherst, Amherst, MA, United States, Eleni Christofa, Eric Gonzales, Jimi Oke

Urban rail transit (URT) systems are crucial for improving the mobility of urban areas, yet they face challenges in effective planning and operation. This research represents an approach to planning train operations, specifically the Massachusetts Bay Transportation Authority (MBTA) urban rail network in Boston. We estimated a vector-to-sequence (vec-to-seq) neural network aimed at improving URT planning by mapping high-level planning metrics to low-level train operating variables. We used a transformer neural network to evaluate the efficient mapping of inputs to outputs. This study offers a generative model trained to map high-level metrics to movement variables, proving its effectiveness in driving energy efficiency.

3 - Optimizing Two-Echelon Autonomous Modular Vehicle Ridesharing and Consolidation Using Reinforcement Learning

Xi Cheng, University of Illinois Chicago, Chicago, IL, United States, Amir Shafiee, Hanieh Rastegar, Jane Lin

This study introduces a novel approach to optimizing two-echelon ridesharing systems through reinforcement learning with autonomous modular vehicle technology (AMVT). In the first echelon, AMVT pods within suburban areas engage in ridesharing, efficiently collecting passengers who have made requests via a mobile app. In the second echelon, occupied pods consolidate into a pod train, minimizing the number of vehicles and optimizing passenger distribution. Unoccupied pods disjoin from the train to continue individual operations, ensuring flexibility and responsiveness to new requests. To prevent congestion near the on-ramp leading to the downtown expressway, the consolidation point is strategically established based on anticipated demand for subsequent passenger pickups. This dynamic and adaptive approach enhances operational efficiency, reduces congestion, and improves passenger experience in urban transportation systems.

4 - Using Autonomous and Modular Vehicle Technology for Integrated Passenger and Freight Transportation

Amir Shafiee, University of Illinois Chicago, Chicago, IL, United States, Xi Cheng, Hanieh Rastegar, Jane Lin

The surge in urban mobility demands, driven by increasing e-commerce and urbanization, requires more efficient and reliable transportation solutions. We proposed a system that employs Autonomous and Modular Vehicle Technology (AMVT) and explore the advantages of passenger and freight co-modality while evaluating the flexibility of modular adjustments. The vehicle’s modules are designed to serve either freight or passengers and can switch roles depending on current demands. Modules within each section are connected, enabling passengers or cargo to transfer between them during the journey, and also reduce energy consumption resulting from platooning. For security, the connection between the passenger and freight sections can be locked. At the start of the day, the total demand for both passenger and freight transport is known, including preferred pickup and delivery time windows and locations. Vehicles depart from a depot in a pre-determined formation and have the capability to alter their configuration at various intersections. The primary objective of this study is to minimize vehicle operating costs by optimizing the route of vehicles, configuring vehicle formations at each node, and efficiently allocating freight. We also aim to identify the most important factors influencing system performance. Through a mixed-integer programming model, we demonstrate how the integration of modular vehicles and co-modality can significantly enhance transportation efficiency and decrease total operation cost compared to traditional systems.

1 - Can LLMs Augment Online Experimentation? Evidence from Headline Selection

Yufeng Zheng, University of Toronto, Toronto, ON, Canada

2 - ORLM: Training Large Language Models for Optimization Modeling

Zizhuo Wang, Chinese University of Hong Kong, Shenzhen, Hong Kong, Hong Kong

Large Language Models (LLMs) have emerged as powerful tools for tackling complex Operations Research (OR) problem by providing the capacity in automating optimization modeling. However, current methodologies heavily rely on prompt engineering (e.g., multi-agent cooperation) with proprietary LLMs, raising data privacy concerns that could be prohibitive in industry applications. To tackle this issue, we propose training open-source LLMs for optimization modeling. We identify four critical requirements for the training dataset of OR LLMs, design and implement OR-INSTRUCT, a semi-automated process for creating synthetic data tailored to specific requirements. We also introduce the IndustryOR benchmark, the first industrial benchmark for testing LLMs on solving real-world OR problems. We apply the data from OR-INSTRUCT to various open-source LLMs of 7b size (termed as ORLMs), resulting in a significantly improved capability for optimiza- tion modeling. Our best-performing ORLM achieves state-of-the-art performance on the NL4OPT, MAMO, and IndustryOR benchmarks.

3 - LLM for the Supply Chain Beer Game

Ming Fan, University of Washington, Seattle, WA, United States, Apurva Jain, Léonard Boussioux, Hongyu Chen

We present a novel approach to designing agentic systems for complex decision-making under uncertainty, using the Beer Game supply chain simulation as a testbed. While state-of-the-art large language models (LLMs) possess advanced human language abilities, they still lack domain-specific knowledge and reasoning capabilities in specialized areas. We explore enhancing ChatGPT's advanced reasoning capabilities to make rational decisions in the context of the bullwhip effect, characterized by demand variability amplification along the supply chain. A Socratic iterative prompting approach is used to iteratively refine prompts and address the deficiency of LLMs in complex decision-making.

4 - Can large language models provide useful feedback on research papers? A large-scale empirical analysis

Hancheng Cao, Stanford University, Stanford, CA, United States

The rapid growth of scholarly production and specialized knowledge challenges conventional scientific feedback mechanisms, making high-quality peer reviews increasingly difficult to obtain. With the advent of large language models (LLMs) like GPT-4, there's growing interest in using them for generating scientific feedback on research manuscripts. However, the utility of LLM-generated feedback has not been systematically studied. To address this, we developed an automated pipeline using GPT-4 to provide comments on full PDFs of scientific papers. We evaluated the quality of GPT-4's feedback through two large-scale studies. First, we quantitatively compared GPT-4's feedback with human peer reviewers' feedback across 15 Nature family journals (3,096 papers) and the ICLR machine learning conference (1,709 papers). The overlap in points raised by GPT-4 and human reviewers (30.85% for Nature journals, 39.23% for ICLR) is comparable to the overlap between two human reviewers (28.58% for Nature journals, 35.25% for ICLR). For weaker papers (rejected ICLR papers), GPT-4's overlap with human reviewers was higher (43.80%). In a prospective user study with 308 researchers from 110 US institutions in AI and computational biology, 57.4% found GPT-4's feedback helpful/very helpful, and 82.4% found it more beneficial than feedback from some human reviewers. Despite its benefits, GPT-4 has limitations, such as focusing on specific feedback aspects and struggling with in-depth critique of method design. Our results suggest that while human expert review remains essential, LLM feedback can complement it, especially when timely expert feedback is unavailable and during early manuscript preparation stages.

Behavioral Decision Analysis

Invited Session

Decision Analysis Society

Chair: Yucheng Su, IE Business School, MADRID, 28006, Spain

Co-Chair: Matthias Seifert, Operations & Business Analytics, IE Business School - IE University, Madrid, Spain

1 - Introducing the Significance Fadeaway Score

Pranadharthiharan Narayanan, Universidade Nova de Lisboa – Nova School of Business and Economics. VAT: PT501559094, Lisbon, Portugal, Sumit Malik

We introduce a simple metric called "significance fadeaway score" (SFS) to examine the robustness of t-test results in experimental studies. SFS assesses the extent to which statistical significance, typically indicated by $p < 0.05$ hinges on extreme values. To compute SFS, we iteratively remove the most extreme data points (one-at-a-time and without replacement) and recalculate p-values. The resulting SFS metric is highly interpretable. For instance, an SFS of 7 means that statistical significance would fade away if we exclude 7% of most extreme data points. We empirically evaluate SFS scores from ~50 published experimental studies in leading marketing journals (JCR and JCP) and find nearly half the studies lose statistically significance if we selectively remove less than 2% of the sample. We believe this result signals a critical reflection point on revaluating our reliance on statistical significance. Notably, p-values are highly sensitive to selective exclusion of small samples, even in the absence of overt outliers.

2 - System Neglect in Newsvendor Decision Making

Yucheng Su, Operations & Business Analytics, IE Business School - IE University, MADRID, Spain, Matthias Seifert, Canan Ulu, SREYAA GUHA

We study the role of system neglect in newsvendor decision making when facing dynamically changing demand conditions. Previous research has shown that probability judgments in response to observing signals of change often suffer from the system neglect bias, in that decision-makers primarily react to the signal itself rather than the environmental system that generated it. In the present paper, we study how system neglect interacts with common biases in inventory decision making, where managers judge probabilities regarding an impending demand shift. We develop an analytic model that predicts empirical newsvendor behavior and compare it to that of a Bayesian risk-neutral agent. We then test our predictions in an experimental study.

3 - How do Newsvendors react to near misses?

Florian Federspiel, INCAE Business School, Escazu, Costa Rica, Robin Dillon-Merrill, Matthias Seifert

We study *when* and *why* repeated near misses in the context of inventory stockouts lead to inappropriate order quantities and risk-taking. Little is known about the behavioral consequences and risks from near misses in inventory decisions. We offer a theoretical foundation and empirical support from several experimental studies to shed light upon a novel bias applicable to newsvendor decision-making, showing that if prior events do not cause the decision maker to reflect on how close a near miss situation could have been to a negative consequence, these repeated events can lead to irrational order quantities increasing one's exposure to stockouts. We demonstrate that as a newsvendor experiences multiple near misses over time without also experiencing stockouts, they will order quantities that increase the risk of exposure to future stockouts. We demonstrate that decision makers in newsvendor contexts are predictably irrational in their reaction to repeated near misses affecting ordering choices going forward.

4 - Incentive-Compatible and Strongly Fair Cake Cutting

Jens Witkowski, Frankfurt School of Finance & Management, Frankfurt, Germany, Rupert Freeman

The classical cake cutting setting is concerned with dividing a resource, modeled by the [0,1] interval, and allocating subintervals to different agents. Preferences of agents are represented by a function over the [0,1] interval with the agent's utility corresponding to the area under the curve for those subintervals they get allocated. A recent result shows that there does not exist a deterministic cake cutting mechanism that is both incentive compatible and even only one of proportional or envy-free (the latter is restricted to non-wasteful mechanisms). In this work, leveraging proper scoring rules, we design a randomized cake cutting mechanism that is ex ante incentive compatible, ex post strongly proportional, and ex post strongly envy-free. This result is tight in the sense that additionally achieving ex post incentive compatibility is impossible as it would violate the aforementioned impossibility result.

5 - Preferences for Wealth Distributions in the Presence of Group Structure

Rupert Freeman, University of Virginia, Charlottesville, VA, United States, Stefano Balietti

We examine individual preferences for wealth inequality in a population that is endowed with group structure. We conduct an online experiment in which we assume that each individual in the population is associated with a single group identity. Using a custom Distribution Builder tool, participants are asked to build their preferred distribution of wealth for various group structures, including the case of separated and well-mixed groups. In the former case, all members of one group are disadvantaged relative to the other, and in the latter, the distribution of wealth is roughly equal across each group. Our results indicate that preferences for inequality differ significantly when group structures are present relative to a baseline case with no group fairness considerations. Our work is relevant to any setting where group fairness considerations are relevant (e.g., hiring, civic participation, public policy, college admissions), and stands in contrast to existing literature on preferences for inequality that does not simultaneously consider inequality at both the individual and group levels.

Global Supply Chains

Contributed Session

Chair: Zhaocheng Zhang, University of Cambridge, Cambridge, N/A, United Kingdom

1 - Designing a Stochastic Supply Chain Network: An Error-based Heuristic

Gang Wang, University of Massachusetts Dartmouth, North Dartmouth, MA, United States

Designing a stochastic supply chain is challenging because demand is often partially observable or unknown in advance. This paper presents an alternative approach to address a three-echelon stochastic supply chain network design with insufficient demand information. We formulate a stochastic mixed-integer program with chance constraints. We identify a lower and upper bound on the value at risk to deal with chance constraints, thus inducing two mixed-integer linear approximations to the stochastic program. We develop a branch-and-price scheme to solve the approximations and a primal heuristic algorithm for initial columns. We then create a heuristic algorithm for solving the original problem by implementing sensitivity analysis and error bound on the approximations. Besides network size, computational experiments find that network design performance depends on aggregate service levels and maximum demand variations. The aggregate behavior of service levels has an inverse impact on the network design performance, while maximum coefficients of demand variations present a positive effect. Computational results reveal that our proposed algorithms perform well compared to normal distributions and a robust optimization formulation. Our models and algorithms suggest a feasible network design tool for handling uncertainties in supply chains.

2 - A Variational Inequality Trade Network Model in Prices and Quantities Under Commodity Losses

Samirasadat Samadi, University of Massachusetts Amherst, Amherst, MA, United States, Anna Nagurney, Ismael Mohammad Pour

Multicommodity trade enables the production, consumption, and flow of commodities across the globe from agricultural ones to precious metals. Mathematical formalisms to model, analyze, and solve such problems have advanced and are also relevant to policy and decision-making. In this paper, we construct a variational inequality trade network model in price and quantity variables, which captures possible losses on transportation routes, which can occur because of perishability of commodities, as in the case of agricultural ones, or outright thefts. The equilibrium conditions are stated and the variational inequality formulation derived. Qualitative properties of existence and uniqueness of the equilibrium supply price, commodity shipment, and demand price pattern are provided under reasonable conditions. Illustrative examples help to demonstrate the model. An algorithm that is proposed yields closed form expressions at each iteration and can also be interpreted as a discrete time adjustment process for the evolution of the economic variables. A spectrum of algorithmically solved numerical examples, with full input and output data provided, yields insights into the impacts of commodity losses, increased congestion, as well as enhanced marketing on producers as well as consumers. This new model expands the scope of spatial price equilibrium modeling under commodity losses.

3 - Tensor Factor Analysis of Global Supply Chains

Zhaocheng Zhang, University of Cambridge, Cambridge, United Kingdom, Weichen Wang, Jing Wu

This paper presents a novel empirical framework for analyzing granular supply chain data. Rather than focusing on supply chain diads, we model the entire global supply chain flows as a higher-order tensor, allowing us to explore the underlying latent lower-dimensional structure of the dynamic supply chain network using recently developed tensor-valued factor models. By examining the latent networks and their connections to the surface networks, we gain a clear view of how supply chains have evolved over the past two decades. The resulting lower-dimensional representation of the dynamic network can then be utilized for second-step analyses, such as predicting the time series of the tensor-valued supply chain network. In addition to the standard factor model, we further introduce characteristic-based factor loadings modeled as unknown functions of country-level and industry-level time-varying covariates. We propose an efficient estimation algorithm for this semiparametric model. The latent lower-dimensional tensor factors estimated from our models capture over 85% of the evolution of global supply chain networks.

Adaptive Strategies in Experimentation and Logistics

Contributed Session

Chair: Yifan Wu, 2250 Dartmouth St, 77840

1 - On the Value of Flexibility for Adaptive Experiments

Huijun Zhu, National University of Singapore, Singapore, Singapore, Yifan Feng, Tu Ni

Adaptive experimentation refers to the practice of changing (improving) the experiment configurations on the fly based on observed data. While it can potentially increase sample efficiency, it potentially needs strong flexibility as an experimenter and thus may be difficult to implement in practice. To explore the interplay between sample efficiency and flexibility in adaptive experiments, we formulate a Bayesian sequential hypothesis testing problem. The goal is to minimize the sum of sampling and penalty costs under different levels of flexibility. Here, flexibility is defined as the number of times one can change the experiments. We show that there is a notable gap between "No Flexibility" (where experiments cannot be changed) and "Full Flexibility" (where experiments can be freely changed adaptively). Nevertheless, the gap can be (asymptotically) closed by just allowing to change the experiment once. That is achieved by an experimentation rule we develop, termed Nested SPRT, which is both simple to derive in closed form and easy to implement.

2 - A vehicle routing problem for massive Covid-19 testing in Antofagasta, Chile

Hernan Caceres, Universidad Catolica del Norte, Antofagasta, Chile, Javiera Auad, Andrea Fernández, Blanca Peñaloza, María-Soledad Zuzulich

The COVID-19 pandemic has demanded massive and recurrent testing due to the high number of cases that have been found in the last two years. Mass testing requires significant resource management to develop, which is why a useful tool to manage them is optimization. A project was developed in Antofagasta, Chile, to help small businesses to have more control over positive cases in their establishments. A medical team would visit them regularly to have greater control and provide them with more security. To do that efficiently, a vehicle routing problem with multiple time windows was developed to optimize the time of visit routes and medical equipment necessary to carry out the testing.

3 - Discrete Event Simulation inside a Private Hospital in Brazil

Reinaldo Crispiniano Garcia, Universidade de Brasilia, Brasilia, Brazil, Joao Gabriel De Souza Vale, Ricardo Accorsi, Antonildes Nascimento Assuncao, Noerci Batistela Junior

The COVID-19 pandemic has had a profound impact on global health systems, leading to unprecedented demand for emergency services and then the need for innovative operational solutions. This research aimed to design a Discrete Event Simulation (DES) model of an Emergency Department (ED) in a Brazilian private hospital to identify process bottlenecks. The studied hospital is one of the main Brazilian Hospitals attending more than 40 thousand patients yearly. The analyzed process had different specialities including pediatrics, orthopedics, geriatrics and neurology ones. Moreover, not only the different arrival rates for each medical practice was considered but also their seasonality and their service rates. It was then observed that just scheduling the physicians according to the patients bottlenecks, it was possible to reduce the patients total time in the system by about 5%. Once the efficiency increase was obtained without raising the systems cost, the applied approach is a promising one to increase the hospitals efficiency in a time of scarce health resources.

4 - Train, then Estimate and Decide

Tarkan Temizoz, Eindhoven University of Technology, Eindhoven, Netherlands, Christina Imdahl, Remco Dijkman, Douniel Lamghari-Idrissi, Willem van Jaarsveld

The effectiveness of data-driven strategies in inventory management is undergoing reevaluation. The COVID-19 pandemic highlighted the limitations of relying solely on historical data as industries worldwide grappled with drastic changes in demand patterns and supply uncertainties. Additionally, there can be scenarios with limited or no historical data, such as new product launches, where data is concurrently acquired with inventory decisions. These challenges are particularly compounded when data is censored, with decision-makers only able to observe sales but not the actual demand or not knowing when the placed orders will come due to supply uncertainty.

Addressing limited, censored data necessitates modeling inventory problems as Partially Observable Markov Decision Processes. In this work, we propose a new framework to solve POMDPs, typically encountered in inventory management when the demand or the lead time distribution is censored. This framework is based on Train, then Estimate and Decide strategy. Specifically, for solving POMDPs corresponding to a generic inventory model, we train a neural network policy over the possible parameter spaces of the unknown or censored variables using deep reinforcement learning. Then, upon collecting possibly censored data with new observations, we estimate the related parameters and feed the trained neural network with them for replenishment decisions.

Experimental results reveal that our framework, equipped with a state-of-the-art DRL algorithm -Deep Controlled Learning- for the training task and Kaplan-Meier Estimator for the estimation task, outperforms the best online learning algorithms in lost sales inventory control. This level of performance is attained using a single neural network policy.

5 - Revisiting Continuous p-Hub Location Problems with the L1 Metric

Yifan Wu, Texas A&M University, College Station, TX, United States, Joseph Geunes, Xiaofeng Nie

Motivated by emerging urban applications in commercial, public-sector, and humanitarian logistics, we revisit continuous p-hub location problems under the L1 metric, where several facilities are to be located in a continuous space such that the expected minimum Manhattan travel distance from a random service provider to a random receiver through exactly one hub facility is minimized. Firstly, some closed-form results are derived for one-dimensional cases and two-dimensional cases up to two hubs. Secondly, we propose a simulation-based approximation method for problems with more than two hubs in two-dimensional cases. Finally, we apply our method to a case study on optimizing public access defibrillator deployment.

The content presented is most relevant to Professional (Mid-Career); Executive (Senior Level); and Associate (Early Career).

2 - Constraints and Coordination for Deep Reinforcement Learning Agents

Carson Eisenach, Amazon, Inc, New York, NY, United States

We explore new techniques for constrained reinforcement learning (RL) in the real-world, specifically as applied to inventory management. The classic approach is to use model predictive control to enforce constraint adherence. With Deep RL policies, this becomes complicated as they consume high-dimensional features to make decisions, and accurately forward simulating this joint distribution is extremely challenging, if not impossible. This session provides an overview of a new approach -- "Neural Coordinator" -- which directly forecasts dual costs under which a policy will adhere to the desired constraints. We will demonstrate its effectiveness in the inventory control setting and cover how to backtest policies in the presence of constraints.

Behavioural Queueing Science and Service Operations

Invited Session

MSOM: Service Operations

Chair: Yichuan Ding, McGill University, Montreal, QC, H3A 1G5, Canada

Co-Chair: Yifeng Cao, University of British Columbia, Vancouver, BC, Canada

1 - Dynamic Transfer Policies for Parallel Queues

Jangwon Park, University of Toronto, Toronto, ON, Canada, Timothy Chan, Vahid Sarhangian

We consider the problem of load balancing in parallel queues by transferring customers between them at discrete points in time. Holding costs accrue as customers wait in the queue, while transfer decisions incur both fixed (setup) and variable costs proportional to the number and direction of transfers. Our work is primarily motivated by inter-facility patient transfers between hospitals during a surge in demand for hospitalization (e.g., during a pandemic). By analyzing an associated fluid control problem, we show that under fairly general assumptions including time-varying arrivals and convex increasing holding costs, the optimal policy in each period partitions the state-space into a well-defined *no-transfer region* and its complement, such that transferring is optimal if and only if the system is sufficiently imbalanced. In the absence of fixed transfer costs, an optimal policy moves the state to the no-transfer region's boundary; in contrast, with fixed costs, the state is moved to the no-transfer region's relative interior. We further leverage the fluid control problem to provide insights on the trade-off between holding and transfer costs, emphasizing the importance of preventing excessive idleness when transfers are not feasible in continuous-time. Using simulation experiments, we investigate the performance and robustness of the fluid policy for the stochastic system. In particular, our case study calibrated using data during the pandemic in the Greater Toronto Area demonstrates that transferring patients between hospitals could result in up to 27.7% reduction in total cost with relatively few transfers.

2 - Foresee the Next Line: Customer Strategies and Information Disclosure in Tandem Queues

Ricky Roet-Green, Simon Business School, University of Rochester, Rochester, NY, United States, Jingwei Ji, Ran Snitkovsky

Many services consist of multiple stages, where each stage requires some waiting before completion. For example, customers who visit the Apple Store join the check-in queue first, and then wait in another queue to be served by the Genius Bar technician. Although customers may observe the queue in front of them, they usually have no information about the waiting situation in the next queue. Our paper aims to examine the impact of queue-length information on customers' strategic behavior in such systems. We assume a two-stage tandem queueing system, with an admission queue followed by a treatment queue. Customers observe the queue length at arrival to each queue; they may balk or join and might later renege. We first study the fully observable model, in which queue-length information of both queues is available to customers at the time they arrive to the system. We calculate the equilibrium strategy and show that it is not necessarily a function of the total number of customers in the system. Next, we study the partially observable model, in which customers observe each queue length only at arrival to it, i.e., they do not observe the second queue length when they arrive to the system. We compare the system performance across the fully and partially observable models. We find that in most cases the partially observable model yields higher throughput but lower social welfare compared to the fully observable model.

3 - Should Multi-Listing be Allowed? Throughput and Social Welfare Analysis

Yichuan Ding, McGill University, Montreal, QC, Canada

We consider a system that consists of multiple service providers (SP), each of which keeps its own waitlist. The service offered by different SPs have similar content and thus a customer, despite having preference between different SPs, can be served by any one of the SPs and leave the system. In this case, some customers may opt to register on multiple waitlists for early access to service. We refer to such queue-joining behavior as “multi-listing”, which is ubiquitous in real life. We analyze the throughput rate and the social welfare in a multi-listing system and derive insights into the management of such a system. We also compare it with other system designs such as a pooling queue or a separate-queue system.

1 - Impact of Successful Drug Launches on Biotech-Pharma Alliance Terminations: A Machine Learning Approach

Pierre Gautreau, York University - Schulich School of Business, Toronto, ON, Canada, Moren Levesque, Annapoornima Subramanian, Vareska van de Vrande

This study investigates the phenomenon of biotech-pharma alliance breakups following successful drug launches by pharmaceutical partners, a vulnerability to young biotech firms unexplored in the current literature. Using a data-driven theory-building approach, we employ machine learning techniques to analyze 3,717 terminated biopharmaceutical alliances from 2000 to 2019, sourced from the Cortellis Drug Discovery database. Our methodology relies on Bayesian Additive Regression Trees (BART) to isolate alliance terminations induced by the pharmaceutical partner’s successful drug launch and evaluates the conditions more likely to yield such termination. Our findings reveal that a successful drug launch by a pharmaceutical partner increases the likelihood of alliance termination by 6%. Notably, pharmaceutical firms with high R&D intensity are less likely to terminate alliances post-launch, indicating the importance of finding a partner that is actively engaged in R&D. Further analysis identifies firm size, failure experience, and the mode of alliance formation (equity versus non-equity alliance) as significant determinants of alliance vulnerability to a pharmaceutical partner's drug launch. The study contributes to the literature on innovation alliances and R&D productivity by demonstrating the premature nature of these terminations, which adversely affect both biotech firms' operational capabilities and the pharmaceutical firms' R&D productivity. Additionally, this research underscores the importance of strategic considerations in alliance formation to mitigate the risks associated with successful drug launches. Our work also provide practical insights for manager to consider when selecting alliance partners.

2 - Patent Pendency and Future Innovative Activities

PARAM PAL SINGH CHHABRA, University of Alberta, Edmonton, AB, Canada, Manpreet Hora, Karthik Ramachandran

We study the effect of patent pendency on inventors’ future innovative activities. We find support for our hypotheses by testing them using inventor-level patent data published by the United States and Patent Trademark Office (USPTO). Our results indicate a negative effect of longer patent pendency on the number and quality of inventors' future patents.

Keywords: patent pendency, inventors, resource allocation, USPTO.

3 - Role of Startup Rating Agencies in Improving Venture Investment Decisions

Thunyarat Amornpetchkul, Santa Clara University, Santa Clara, CA, United States

The emergence of startup rating agencies in the contemporary startup ecosystem has sparked interest but remains largely unexplored in academia. These agencies offer rigorous evaluations and due diligence on ventures, potentially enhancing insights into their success prospects. However, their services typically come at a cost, either in the form of a fixed fee or an equity share. This study aims to identify the circumstances under which an investor finds it beneficial to engage startup rating agencies to obtain more accurate venture information for informed investment decisions. We analyze the investor’s optimal decisions under two payment schemes: a fixed fee scheme and an equity share scheme, and subsequently determine the conditions under which each scheme is preferable. Additionally, we analyze the problem from an entrepreneur’s perspective to see when it would be worthwhile for her to pay for a startup rating agency’s service herself, expecting to influence the investor’s decisions in her favor. Through these analyses, we aim to provide a comprehensive understanding of the implication and efficacy of startup rating agencies in improving venture investment outcomes.

4 - Emerging-Economy Patent Regulation Reforms and Firm Innovativeness Abroad

Xiaojin Liu, Virginia Commonwealth University, Richmond, VA, United States, Pankaj Kumar, Aks Zaheer

Emerging-economy firms are making significant efforts to move up the value chain by improving their innovativeness and increasing innovations abroad. We investigate whether and under what conditions patent regulation reforms in emerging economies affect these firms’ outward innovation behavior. Our result highlights that emerging-economy firms become more internationally competitive post-reform.

5 - A Machine Learning Approach to Predicting Project Performance

siqi wang, University of California, San Diego, La Jolla, CA, United States, Xiaochen Gao, Sina Khorasani, Vish Krishnan, Lakshminarayana Nittala

We use a massive U.S. government dataset to predict cost overrun and schedule delay in government contracts. Despite facing a high-dimensional dataset, we manage to build a well-performing CatBoost model with exceptionally high prediction accuracy. We identify top predictors for cost and schedule overruns, interpret our predictions using SHAP values, and offer recommendation based on causal models that could lead to substantial time and cost savings.

Optimizing Data Center Operations and Sustainability

Contributed Session

1 - Data Value in Distribution System Operations

Mehrnoush Ghazanfariharandi, Rutgers University, Piscataway, NJ, United States, Robert Mieth

The rise of advanced data technologies in electric power distribution systems enables operators to optimize operations, but raises concerns about data security and consumer privacy. Resulting protection mechanisms that alter or obfuscate datasets may invalidate the efficacy of data-driven decision-support tools and impact the value of these datasets. This paper derives tools for distribution system operators to enrich data-driven operative decisions with information on data quality and, simultaneously, assess data usefulness in the context of this decision. To this end, we derive an AC optimal power flow model for radial distribution systems with data-informed stochastic parameters that internalizes a data-quality metric. We derive a tractable reformulation and discuss the marginal sensitivity of the optimal solution as a proxy for data value. Our model can capture clustered data provision, e.g., from resource aggregators, and internalize individual data quality information from each data provider. We use the IEEE 33-bus test system, examining scenarios with varying photovoltaic penetration, to demonstrate the application of our approach and discuss the relationship between data quality and its value.

2 - Momentum Power Forecast: A Statistical Benchmark to Improve Google's Data Center Capacity Planning

Lijuan Xu, Google, Mountain View, CA, United States

Google builds a global footprint of data centers to support our products and services. Accurate and cross functionally aligned demand forecasts are essential to inform the right data center capacity strategies and coordinate the various planning activities. Over decades of learning and practice, we developed the "human-in-the-loop" forecasting framework to integrate data science with business planning. In this talk, we are happy to share the behind-the-scenes cooking of our statistical benchmark power forecasts that bring forecasting, metrics, and engineering automation all together to influence Google's business planning in the data center space.

3 - Predicting Potential Uncorrectable Errors Using Telemetry AI Modeling for Data Center Reliability

Youngmin Lee, Samsung Electronics, Hwaseong, Korea, Republic of
